Royal Horse Artillery:—Shropshire: Surgeon-Captain George Mackie to be Surgeon-Major (dated August 4th, 1914).

London Mounted Brigade Field Ambulance: Thomas Hillier Chittenden to be Major. James Wilson McIntosh (late Lieutenant, Royal Army Medical Corps, Territorial Force) to be Captain. The undermentioned to be Lieutenants: William Francis Smartt, Harold Edward Gibson, and Duncan Frederick Macrae.

Scottish Horse Mounted Brigade Field Ambulance: Major Samuel Macfarlane Sloan, from Attached to Units other than Medical Units, to be Lieutenant-Colonel. Hugh Richardson (late Captain R.A.M.C., T.F.) to be Major.

2nd Northumbrian Field Ambulance: Arthur Langford Bastable to be Lieutenant.

3rd East Anglian Field Ambulance: Major Josiah Oldfield to be Lieutenant-Colonel. Leonard Robert Tosswill (late Captain, 1st Wessex Field Ambulance, Royal Army Medical Corps) to be Lieutenant.

1st West Riding Field Ambulance: Captain Alexander B. S. Stewart to be Major.

2nd West Riding Field Ambulance: Captain Charles W. Eames to be Major (temporary).

2nd South Midland Mounted Brigade Field Ambulance: Captain Alfred W. Moore to be Major.

1st South-Western Mounted Brigade Field Ambulance: Major George Rodway Swinhoe, retired list, Territorial Force, to be Major.

2nd South-Western Mounted Brigade Field Ambulance: Louis Joseph Edward McHugh to be Lieutenant.

2nd West Lancashire Field Ambulance: Captain William Macdonald to be Major.

3rd West Lancashire Field Ambulance: Captain Ernest Knight, from the Territorial Force Reserve, to be Captain.

1st London (City of London) Field Ambulance: Eliezer Coplans and David Jobson Scott to be Lieutenants.

2nd London (City of London) Field Ambulance Hubert Charles Phillips (late Captain, Royal Army Medical Corps) (Volunteers) to be Captain. Honorary Lieutenant in the Army William Ernest Rielly to be Captain. William Gibbs Lloyd to be Lieutenant.

3rd London (City of London) Field Ambulance: Myer Coplans to be Captain. Stanley Wyard and Cedric Rowland Taylor to be Lieutenants.

5th London Field Ambulance: The undermentioned to be Lieutenants: Alfred Hugh Bell, John MacMillan, Hector Mackay Calder, and Maurice Ulick Wilson. Harold Marshall Lambert to be Transport Officer, with the honorary rank of Lieutenant. Herbert Ernest Balfern Ware to be Quartermaster, with the honorary rank of Lieutenant.

3rd Wessex Field Ambulance: James Kearney to be Lieutenant.

Welsh Border Mounted Brigade Field Ambulance: Captain Douglas C. L. Orton to be Major.

4th London Field Ambulance: John Muir (late Captain, Royal Army Medical Corps, Territorial Force) to be Captain.

6th London Field Ambulance: John Edmund Bishop Wells (late Surgeon-Captain, 1st Volunteer Battalion, The Bedfordshire Regiment) to be Major.

Eastern Mounted Brigade Field Ambulance: Lieutenant Claudius G. K. Sharp to be Captain and James MacBain Taylor to be Lieutenant.

3rd Highland Field Ambulance: Captain Alexander E. Kidd to be Major. The undermentioned to be Lieutenants: John Strathearn and George Bruce Killoh.

1st South Midland Field Ambulance: Gerard Thomas Andrewes Uthwatt to be Transport Officer, with the honorary rank of Lieutenant.

2nd North Midland Field Ambulance: Robert Burton Meikle Yates (late Cadet, Sedbergh School Contingent, Junior Division, Officers Training Corps) to be Lieutenant.

Home Counties Clearing Hospital: Major James S. Warrack to be Lieutenant-Colonel.

Attached to Units other than Medical Units.—Captain Henry A. Rudyard to be Major. Captain John R. Williams to be Major. To be Captains: Captain Thomas Mahon Morton, from the Territorial Force Reserve, Lieutenant Arthur L. Heiser, Lieutenant Arthur E. Gladstone, Henry Neville Burroughes (late Captain, 1st London (City of London), General Hospital, Royal Army Medical Corps), Henry William Laing, Lieutenant James L. Joyce, Lieutenant James McHoul, Wilfred Ernest Alderson (late Captain, Royal Army Medical Corps, Territorial Force), and Captain William Thomas Ritchie, from the 2nd Scottish General Hospital. To be Lieutenants: George Finch, Harold Fitzwilliam Comyn, Alfred Herbert Tresham Andrew, John Archibald Thomson, John Clarke, Alexander Anderson, Reginald Douglas Gawn, John Arthur Parsons, Dugald Charles Bremner, Sidney Herbert Clarke, Frank Herbert C. Watson, Robert McAdoo, Sydney James Clegg, George Herbert Hind Manfield, and John G. Morgan (late Lieutenant, 2nd Welsh Brigade, Royal Field Artillery).

DEATHS IN THE SERVICES.

Deputy Surgeon-General Edward McKellar, I.M.S. (retired), at Brighton on Oct. 27th. He saw service in the Burmese war and the Indian Mutiny, and was a member of the Abyssinian Expedition. He attained the rank of deputy surgeon-general in 1877.

Temporary Surgeon A. E. F. Kynaston, R.N., of H.M.S. *Devonshire*, on Oct. 13th, at Dunskaith Hospital, from enteric fever.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8377 births and 4788 deaths were registered during the week ended Saturday, Oct. 24th. The annual rate of mortality in these towns, which had declined from 15·7 to 13·4 per 1000 in the four preceding weeks, rose in the week under notice to 13·8 per 1000 of their aggregate population, estimated at 18,120,059 persons. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 13·2, against a corresponding rate of 13·3 per 1000 in London. Among the several towns the death-rate last week ranged from 3·5 in Wimbledon, 4·9 in Acton, 5·9 in Ealing, 6·1 in Bournemouth, and 6·4 in Hornsey, to 17·0 in Sunderland, 17·2 in Great Yarmouth, 19·7 in Exeter, 20·0 in Huddersfield, 21·1 in Liverpool, and 22·3 in Birkenhead.

The 4788 deaths from all causes were 135 in excess of the number in the previous week, and included 540 which were referred to the principal epidemic diseases, against numbers declining from 1437 to 529 in the five preceding weeks. Of these 540 deaths, 269 resulted from infantile diarrhœal diseases, 101 from measles, 79 from diphtheria, 37 from scarlet fever, 35 from whooping-cough, and 19 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·6, against 1·5 per 1000 in the previous week. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had steadily declined from 1223 to 322 in the five preceding weeks, further fell to 269, and included 76 in London, 32 in Liverpool, 17 in Birmingham, 9 in Sheffield, 8 in Manchester, and 7 in Nottingham. The deaths referred to measles, which had been 61, 73, and 67 in the three preceding weeks, rose to 101 last week, of which 22 were registered in London, 11 in Liverpool, 10 in Manchester, 9 in Leeds, 7 in Birmingham, 7 in Oldham, 6 in Birkenhead, and 6 in Newcastle-on-Tyne. The fatal cases of diphtheria, which had been 63, 57, and 59 in the three preceding weeks, further rose to 79 last week; 30 deaths occurred in London, 4 each in Stoke-on-Trent, Birmingham, and Middlesbrough, and 2 each in Tottenham, Portsmouth, Southampton, Devonport, Bristol, and Hull. The deaths attributed to scarlet fever, which had been 29, 31, and 29 in the three preceding weeks, rose to 37 last week, and included 7 in Manchester, 5 in Liverpool, 5 in Birmingham, 3 in London, 2 in Ipswich, and 2 in Preston. The deaths referred to whooping-cough, which had been 50, 47, and 38 in the three preceding weeks, further declined to 35 last week, of which 8 were recorded in London and 2 each in Plymouth, Birkenhead, St. Helens, Leeds, Sheffield, and Cardiff. The fatal cases of enteric fever, which had been 23, 17, and 14 in the three preceding weeks, rose to 19 last week, and included 3 in London, 2 in Liverpool, and 2 in Stockton-on-Tees.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 4473 in the nine preceding weeks, had further risen to 4616 on Saturday last; 657 new cases were admitted during the week, against 640, 670, and 650 in the three preceding weeks. These hospitals also contained on Saturday last 1481 cases of diphtheria, 69 of enteric fever, 38 of whooping-cough, and 32 of measles, but not one of small-pox. The 1273 deaths from all causes in London were 68 in excess of the number in the previous week, and corresponded to an annual death-rate of 14·7 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 110 to 178 in the five preceding weeks, further rose to 191 in the week under notice, and were 40 above the number registered in the corresponding week of last year.

Of the 4788 deaths from all causes in the 97 towns, 200 resulted from different forms of violence and 402 were the subject of coroners' inquests, while 1448 occurred in public institutions. The causes of 48, or 1·0 per cent. of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Bradford, Hull, and in 56 other smaller towns. Of the 48 uncertified causes of death, 13 were registered in Birmingham, 10 in Liverpool, and 2 each in Stoke-on-Trent, Preston, Barrow-in-Furness, Darlington, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1213 births and 659 deaths were registered during the week ended Saturday, Oct. 24th. The annual rate of mortality in these towns, which had been 15·6, 15·9, and 14·7 per 1000 in the three preceding weeks, rose to 15·0 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 14·4, against 13·2 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 1·2 in Clydebank, 7·9 in Ayr, and 11·3 in Motherwell, to 19·6 in Aberdeen, 20·6 in Kilmarnock, and 22·8 in Kirkcaldy.

The 659 deaths from all causes were 13 in excess of the number in the previous week, and included 80 which were referred to the principal epidemic diseases, against 96 and 81 in the two preceding weeks. Of these 80 deaths, 31 resulted from infantile diarrhœal diseases, 19 from diphtheria, 16 from scarlet fever, 9 from whooping-cough, 4 from enteric fever, and 1 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against 1·6 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 52, 54, and 29 in the three preceding weeks, slightly rose to 31 last week, and included 16 in Glasgow, 5 in Motherwell, and 3 in Dundee. The deaths referred to diphtheria, which had increased from 4 to 19 in the five preceding weeks, were again 19 last week, of which 7 were registered in Aberdeen, 5 in Edinburgh, 4 in Glasgow, and 2 in Kirkcaldy. The fatal cases of scarlet fever, which had risen from 6 to 16 in the five preceding weeks, were again 16 last week, and included 8 in Glasgow and 6 in Aberdeen. The deaths attributed to whooping-cough, which had been 13, 8, and 10 in the three preceding weeks, were 9 last week, of which 7 occurred in Glasgow. The 4 deaths referred to enteric fever were slightly below the average in recent weeks, and comprised 3 in Glasgow and 1 in Falkirk. The fatal case of measles was recorded in Dundee.

The deaths referred to diseases of the respiratory system, which had increased from 62 to 89 in the five preceding weeks, were again 89 in the week under notice; 21 deaths resulted from various forms of violence, against numbers rising from 20 to 29 in the four preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 575 births and 365 deaths were registered during the week ended Saturday, Oct. 24th. The annual rate of mortality in these towns, which had been 17·3, 15·4, and 16·2 per 1000 in the three preceding weeks, declined to 15·8 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 16·9, against corresponding rates of 13·2 and 14·4 per 1000 in the English and Scotch towns respectively. The annual death-rate last week ranged from 15·3 in Dublin (against 14·7 in London and 15·1 in Glasgow), 16·9 in Belfast, 17·0 in Cork, 8·9 in Londonderry, 20·3 in Limerick, and 22·8 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 14·0 per 1000.

The 365 deaths from all causes were 10 fewer than the number in the previous week, and included 44 which were referred to the principal epidemic diseases, against 53 and 57 in the two preceding weeks. Of these 44 deaths, 21 resulted from infantile diarrhœal diseases, 9 from whooping-cough, 7 from measles, 5 from scarlet fever, and 2 from enteric fever, but not one from small-pox or from diphtheria. The mean annual death-rate from these diseases was equal to 1·9, against corresponding rates of 1·6 and 1·8 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had steadily declined from 74 to 33 in the five preceding week, further fell to 21 last week, of which 11 were registered in Dublin and 6 in Belfast. The deaths referred to whooping-cough, which had fallen from 9 to 3 in the four preceding weeks, rose to 9 last week, and comprised 8 in Belfast and 1 in Cork. The 7 fatal cases of measles, which were all registered in Belfast, were 3 in excess of the average in the four preceding weeks. The deaths attributed to scarlet fever, which had been 2, 4, and 7 in the three preceding weeks, fell to 5 last week, of which 2 occurred in Waterford. The fatal cases of enteric fever were recorded in Belfast and Ballymena.

The deaths referred to diseases of the respiratory system, which had been 58, 56, and 71 in the three preceding weeks, fell to 60 in the week under notice. Of the 365 deaths from all causes, 126, or 35 per cent., occurred in public institutions, and 4 resulted from different forms of violence. The causes of 10, or 2·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes last week did not exceed 1·0 per cent.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Care of the Wounded at a Field Hospital.

I PROPOSE to describe from personal experience,[1] and in brief language, the manner in which the wounded are being handled in the French lines. In the first instance, during the rush of wounded that follows an action, all that can be done in a field hospital is to apply an antiseptic dressing, or adjust any first aid dressing that may have already been applied on the field of battle. The dressing for the purpose with which all our soldiers are supplied is an excellent one so long as the bandage which serves to keep it in place is not pulled too tight—which will happen, but which should of course be detected by the usual symptoms. At the ambulance hospital the ligatures necessitated by persistent hæmorrhage should be applied, and fractures set; this is done. Where wounds have been soiled by earth or by contact with filthy straw in ambulance wagons a preventive injection of antitetanic serum is the regulation treatment; it must be given at once to be of any effect. The immediate extraction of bullets and shrapnel is undertaken at the ambulance hospital in simple cases, but location of the projectile by radiography and radioscopy can only be seriously undertaken in clearing hospitals, or better still in the hospitals at the base, though the general advice is that it should be attempted at the earliest opportunity. The Service de Santé possesses a certain number of radiography plants, very well fitted up, mounted on strong automobiles and accompanied by specialists. But the development of the plates calls for a more peaceful environment than is found in hospitals within the collecting zone, and there is natural reluctance to send these costly equipages, of which the number must be limited, too near the fighting line. Already some of them have come under fire. Amputations are rarely done at the ambulance hospitals, save where there is vast destruction of the limbs by shell, with shattering of the bones and conditions that must be followed by immediate and abundant suppuration. The extensive wounds caused by shrapnel rapidly become septic. As long as only the skin and muscles are affected methodical disinfection by hydrogen peroxide solution or tincture of iodine is very valuable, and the employment of hot air, iodine vapour, combined with a current of oxygen will in more or less time lead to good cicatrisation. When there are fractures with much bone exposed the chance of saving the limb becomes very slender, and in many cases delay, with the hope of escaping amputation, is harmful to the patient, who undergoes the operation in the end after long suppuration. Gaseous gangrene, a condition which is almost unknown in civil practice, has occurred in some cases, and is an ominous complication. Prompt amputation does not always avoid a fatal issue, as the tissues have often been infected beyond the apparent limits. Injections of oxygen made into the deep parts of the tissues, according to the method of Dr. Thiriar, of Brussels, will here render signal service, but tubes of compressed oxygen are not at hand everywhere for immediate use. In default of these, injections of hydrogen peroxide can be made into the tissues beyond the infected area. General Delorme, Inspector General of the Military Medical Service, has quite properly and publicly insisted upon the value of this excellent technique. Unfortunately these injections are very painful, the solution for the sake of preservation being always acid; if it becomes alkaline it decomposes. Sodium perborate, however, allows of neutralisation without decomposition, and its use ought to be widely advocated. Wounds caused by rifle bullets, when they do not hit the cranium, the thorax, or the pelvis, and do not break any bones, are often wonderfully benign. Grooved or channelled shot wounds usually heal spontaneously within a few days if care has been taken promptly to cover up the two orifices; the bullet is, as a matter of fact, rendered aseptic by the temperature which it reaches during its flight. These wounds only become infected where a portion of the uniform is carried into the tissue by the projectile, or if the openings of the wound are contaminated by soil or the contact of dirty garments. This is now universal experience in war. Dum-dum bullets are stated to be employed by the Austrians, having been found in their cartridge pouches; too much stress, however, must not be laid upon the statement with regard to these bullets in view of the extensive damage which may be caused by an ordinary shot. The German bullet is made of compressed lead surrounded by a rather thin metallic cover, and it is not rare for this latter, when in contact with a bone, to be detached from the body of the projectile and become jagged and split up into many fragments without any explosive force or any cut-off end of the shot being required to produce such effect. The damage done is then formidable. One of these misshapen bullets can burrow a hole in a thigh large enough to take the fist; the injury is, however, only the effect of an ordinary projectile. Bullets which happen to become deformed by a ricochet, or which rebound on a stone or on a wall, afterwards act in the same fashion. Beyond these cases an ordinary bullet during its flight may at a certain point in its course rock or see-saw on its axis; its base being heavier than its apex it describes then, not a right line or a regular parallel, spiral, or helical course, but receives a motion which causes it to produce a funnel-shaped or infundibular entry to the wound. All these facts must be known before deciding upon the existence or otherwise of an explosive or a soft-nosed bullet.

---

[1] Our regular Paris correspondent writes in his covering letter [illegible] follows: "Je suis encore hors de Paris, où je suis retenu par mes fonctions de médecin chef d'un hôpital à la frontière."

The late Emile Reymond.

I am unfortunately unable to mention here individually all my French *confrères* who have fallen victims to this cruel war, but I wish at least to record the recent glorious death of one of our most esteemed surgeons, Dr. Emile Reymond. Born in 1865 at Tarbes, he became interne of the hospitals in 1891. He was laureate of the Institute and member of the Faculty of Medicine and of the Assistance Publique, and held in turn the posts of chef de clinique at the Faculté, surgeon to the Hôpital de Sèvres, and later to the departmental hospital of Nanterre. At first he did much important work in gynæcology. With his master, Terrier, he then led the way in heart suture, and in 1903 the Association Française de Chirurgie commissioned him, with Terrier, to report upon the surgery of the heart and pericardium. He became first Deputy, then Senator, for the Department of the Loire. From the inception of aviation he enthusiastically devoted himself to aerial locomotion, soon taking rank among the leading pilots. At the outset of the war, in spite of his 49 years of age, he entered as a volunteer in the military flying corps, although he held the rank of médecin-major in the Medical Service. He fulfilled his duties with conscientiousness, courage, and self-sacrifice. While reconnoitring over the enemy's positions the Germans fired on his machine, and Dr. Reymond was seriously wounded. He descended between the German and French lines. He was at once picked up and removed to hospital, where he died of his wounds, not, however, before he had been able to convey the valuable information he had been sent out to seek. The Commanding-General decorated him on his death-bed.

Medical Affairs in Paris.

The meetings of the Académie de Médecine are naturally taken up with communications bearing on the surgery of war, and the diseases especially connected therewith. Recent communications made to the Academy of Sciences and the Academy of Medicine on the part of General Delorme, Inspector-General of the French Military Medical Service, by Dr. Tuffier, Dr. Capitan, Dr. Picqué, M. Walther, and Dr. Pierre Delbet, have, thanks to the press, quickly reached our medical officers in the fighting areas, and have proved very valuable. When the war is over the medical observations now accumulating will form material of the highest scientific interest. M. Walther has studied the etiology and prophylaxis of tetanus among the wounded in war, and M. Capitan wounds of the thorax induced by the German rifle ball. M. Tuffier, who was sent by the Ministry of War to the various military medical establishments, has communicated his conclusions on the surgery of war. M. Lucien Picqué has devoted attention to the preservation of the limb in cases of wounds of the soft parts and fractures of the shafts of the long bones. Professor Pierre Delbet has submitted to the Academy an apparatus that he has used for ten years for the treatment of complicated fractures of the arm, for which he claims great advantages, especially from the standpoint of conservative surgery, and which procures immediate relief from suffering. Under its use dressings are no longer painful and consolidation takes place under the best conditions, and more rapidly than with any other apparatus. Finally, the Academy has received a communication of a more peaceful character, relating to the use of the milk given by cows collected in concentration camps at Paris. The production of this herd exceeds 8000 litres a day, and is divided among 85 hospitals, mairies, and assistance bureaux. Professor Pinard finds that this milk gives universally excellent results.

Oct. 27th.

ROYAL FREE HOSPITAL: LONDON SCHOOL OF MEDICINE FOR WOMEN.—In consequence of the war it has been decided to postpone the annual dinner usually held on the second Wednesday in December.

MASTERSHIP OF THE COOMBE HOSPITAL, DUBLIN.—Dr. R. A. McLaverty has been elected Master of the Coombe Lying-in Hospital in succession to Dr. Michael J. Gibson, whose period of office ends in December. The post is much sought for, as the Coombe Hospital has in recent years gained much ground as a teaching centre.

Obituary.

ANTHONY TRAILL,

PROVOST OF TRINITY COLLEGE, DUBLIN.

Dr. Anthony Traill, Provost of Trinity College, Dublin, who died on Oct. 15th, though he never practised medicine, was, since 1869, a member of the medical profession. He was the first medical man to hold the office of Provost, and it is of interest to note that contemporaneously with his rule in Trinity College two of the four other colleges in Ireland of university rank—University College, Dublin, and University College, Cork—have also been ruled by medical men. Anthony Traill was born in co. Antrim in 1838. He entered Trinity College in 1855, graduated with high honours in 1860, and became a Fellow of the College in 1865. He devoted himself thereafter to making himself familiar with the sources of study in the professional schools of the College, and took in succession degrees in law and medicine. For many years he had a close association with the School of Engineering, and was himself a pioneer in the department of electrical engineering; he had an active share, with Lord Kelvin and others, in the construction of the Portrush and Giant's Causeway electric railway, the first of its kind in the world. In 1904 he was appointed Provost. He came to rule over his College at a critical period, and it is in large part due to his firmness and courage that the College emerged unscathed and strengthened from the melting-pot of Irish university institutions. He gave cordial assistance to the Government in its fruitful endeavours to solve the problem of Irish university education. During his provostship several notable reforms took place in Trinity College, of which perhaps the admission of women on equal terms with men was of the greatest public interest. In the progress of the medical school Traill took an active interest, and he entered with zest into the arrangements for the bicentenary celebrations in 1912. Soon after his elevation to the provostship he was elected an Honorary Fellow of the Royal College of Physicians of Ireland and of the Royal College of Surgeons in Ireland. He held honorary doctorates from the Universities of Glasgow, Aberdeen, and St. Andrews.

A man of affairs rather than a scholar, Dr. Traill had great administrative ability and indomitable energy. Without much grace of manner he had solid qualities of head and heart. He had no distaste for controversy, but he was singularly free from personal bitterness. Neither friend nor opponent ever doubted his absolute honesty and straightforwardness. Greater scholars than Traill have guided the fortunes of Trinity College in the past; none has served her with more single-minded and untiring devotion; few have rendered her more solid service.

A well-known Belfast physician sends us the following more intimate notes upon the career of Dr. Traill: "Traill was a typical Ulsterman, while since the foundation of Trinity College, Dublin, by Queen Elizabeth in 1592, although he was the forty-fifth Provost, he was only the fourth layman to occupy this position and the first and only graduate in medicine to be so honoured. He was a very strong personality. He had a splendid academic standing, he held every position of importance at Trinity College, was a graduate in arts, law, and medicine, and when he gained the coveted fellowship he presented himself for examination in mathematics, experimental science, Hebrew, and philosophy. He was also a very favourite tutor, and during his years as tutor Fellow he had over 900 pupils. As an athlete he was in his time captain of the University cricket eleven; he was one of the founders of the college races in 1857; on 14 different occasions he was racquet champion of his University, holding this cherished position when he was actually 51 years of age; for many years he shot at Wimbledon with the Irish eight; and in more recent times he was an enthusiastic golfer, his handicap when he was 65 years of age being only five. Further, he was a good shot, an excellent fisherman and mountain climber, and a member for many years of the Alpine Club. Then he was an excellent man of business, and Trinity College owes much to his splendid work in ably re-arranging her finances. But, above all else, Dr. Traill was a born fighter on behalf of any cause or person he supported, and one of the very best of friends. Under a pugnacious exterior there beat the kindest and truest of hearts."

LIBRARY OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—The annual report recently issued by the librarian of the Royal College of Physicians states that changes have recently been made in the structure of the College which will tend to the greater comfort of readers. One of the committee rooms has been enlarged and the books formerly stored in it have been moved to a new gallery in the library. The entire sum available each year for purchases is only £110, of which £92 are spent on the purchase and binding of journals. It is obvious that the remainder is inadequate to keep up a modern supply of books, and the library committee appeals to Fellows to assist the College by gifts of books. The librarian is endeavouring to make as complete as possible the collection of medical works by Irish writers and of medical works published in Ireland.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held last week Mr. J. W. B. Hodsdon was elected President of the College for the ensuing year. Mr. Hodsdon has been a member of the Council and the representative of the College on the General Medical Council for a number of years. At the same meeting the following gentlemen, having passed the requisite examinations between July 6th and 11th, were admitted Fellows: Thomas Stevens Allen, M.R.C.S. Eng., L.R.C.P. Lond., London; Arthur James Ballantine, M.B., Ch.B. Edin., Cape Town; Norman Hay Bolton, M.B. Ch.B. Edin., Nottingham; Henry Harvard Davis, M.R.C.S. Eng., L.R.C.P. Lond., Glamorgan; Henry Ernest King Fretz, L.R.C.S. Edin. (triple qual.), London; William Gordon Goudie, M.B., Ch.B. Glasg., Glasgow; David Livingstone Graham, M.B., Ch.B. Glasg., Captain Indian Medical Service; John Donald Gunn, M.B., Ch.B. Edin., Edinburgh; Douglas James Guthrie, M.D. Edin., Edinburgh; Arthur Joseph Gordon Hunter, M.D. Edin., Linlithgow; John Brown Dalzell Hunter, M.B., Ch.B., Glasg., Captain Indian Medical Service; Frederic George Lloyd, M.R.C.S. Eng., L.R.C.P. Lond., London; Richard Mainwaring Mainwaring-White, M.D. Edin., Cheshire; Francis Leslie Nash-Wortham, M.R.C.S. Eng., L.R.C.P. Lond., Edinburgh; John William Pell, L.R.C.S. Edin. (triple qual.), Hupeh, Central China; Garfield Arthur Platt, L.R.C.S. Edin. (triple qual.), &c., Ontario, Canada; Edmund Lewis Reid, M.B., Ch.B. Aberd., Banffshire; James Wilson Richardson, M.R.C.S. Eng., L.R.C.P. Lond., &c., Calgary, Alberta, Canada; Sydney James Simpson, M.B., Ch.B. New Zealand, Essex; Leslie Joseph Thompson, M.B., Ch.B. New Zealand, Feilding, New Zealand; Denis Byrne Walshe, M.B., B.S. Melb., Thames, New Zealand; Russell Ernest Walker, M.B., Ch.B. Edin., Peterborough; and Walter Quarry Wood, M.B., Ch.B. Edin., Edinburgh.

Correspondence.

"Audi alteram partem."

SIR JAMES Y. SIMPSON AND ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In his delightful Harveian Oration Sir R. Douglas Powell attributes the discovery of anæsthesia to Sir James Y. Simpson. By a curious coincidence, on the very day on which I heard the address I received from Sir Alexander Simpson the proof sheets of a letter written in April, 1870, to Dr. Bigelow, of Boston, in which Sir James Simpson repudiates anything so "wild or extravagant" as that he used chloroform as an anæsthetic before ether. Thirteen months had elapsed; and later in the letter, discussing the rival claims of Jackson, Wells, and Morton, he decides in favour of Morton, saying that he was "the gentleman to whom I believe the profession and mankind are really and truly indebted for first reducing into practice the production of insensibility by ether inhalation, with the object of annihilating pain in surgical operations." The splendid work which Sir James Simpson did in those early days can never be forgotten, but it is unjust to his memory to attribute to him, as is so often done in this country, a discovery which had become "the blessed possession of the whole world" (to use a phrase of Professor Welch) before the introduction of chloroform.

I am, Sir, yours faithfully,

Oxford, Oct. 26th, 1914. WILLIAM OSLER.

WANTED, A DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Norman Butler's two cases, observed with care and reported in THE LANCET of Oct. 24th, are so lucidly described as to make their diagnosis for the neurologist a matter of comparative simplicity. They belong to a group of acute toxi-infective diseases of the nervous system in which are distinguished four main subdivisions—acute ascending meningomyelitis, acute toxic polyneuritis, acute poliomyelitis or polioencephalomyelitis, and Landry's paralysis.

The first of these is excluded mainly by the absence of any sensory changes and the absence of any sphincter impairment of any duration. The second is excluded partly for a similar reason—viz., the absence of sensory symptoms or signs such as are constant in multiple neuritis, though it is true Dr. Butler's second case had transient pains. The third class, acute poliomyelitis, is more difficult to exclude, for there is an ascending type the symptoms of which are not unlike those of Dr. Butler's cases. Even in the ascending cases, however, the affection is not, as a rule, as symmetrical as it appears to have been in his, and, further, the excellence of the recovery in them is far from common in universal poliomyelitis.

Dr. Butler's cases come most readily under the category of Landry's paralysis, acute ascending motor paralysis of central origin. It is true that in various recent epidemics of poliomyelitis ascending cases have been described as of the Landry type, and some have gone so far as to deny any clinical or pathological entity to Landry's paralysis. But the present state of our knowledge does not justify this generalisation, while it must not be forgotten that Farquhar Buzzard and others have recorded cases of this acute ascending motor paralysis in which the infective agent was not the virus of poliomyelitis. There are, besides, certain minor points in the type of motor palsy which are met with in Landry's paralysis and not in poliomyelitis.

As to the morbid agent in Dr. Butler's cases, it is unwise to hazard any suggestion. Whether it was toxic or infective must remain obscure, although examination of the cerebro-spinal fluid might have proved of considerable value. In any case the condition was probably one of infection of the ascending lymph streams through the spinal cord and lower brain stem, involving almost exclusively the ventral cornua of grey matter. The explanation of this specific action is still unknown; but in certain cases the syphilitic virus has been found to invade the ventral horns exclusively in a similar fashion—so-called syphilitic poliomyelitis. A case of this sort, in which the pathological findings corroborated the clinical view taken of the case, was published by Professor Léri, of Paris, and myself in the *Nouvelle Iconographie de la Salpêtrière* (1904).

Dr. Norman Butler is to be congratulated on the precision with which he has worked out these two interesting cases, which are of undoubted documentary value.—I am, Sir, yours faithfully,

S. A. KINNIER WILSON.

Harley-street, W., Oct. 24th, 1914.

SHELL WOUNDS IN MODERN NAVAL WARFARE.

To the Editor of THE LANCET.

SIR,—In the article with the above title which I jointly contributed to your issue of last week a mistake has crept in which I should be grateful if you would correct. The vaccine was not made by Messrs. Parke, Davis, and Co., but was prepared in the inoculation department of St. Mary's Hospital and under the supervision of Sir Almroth Wright, who has generously sent a stock for Admiralty use through the Medical Director-General.

I am, Sir, yours faithfully,

BRYAN PICK,

Shotley, Oct. 26th, 1914. Staff-Surgeon, R.N.

THE NATIONAL MEDICAL UNION AND THE £90,000 WINDFALL TO PANEL DOCTORS.

To the Editor of THE LANCET.

SIR,—In the interest of the general public and the medical profession the council of the National Medical Union has deemed it expedient to lodge with the Insurance Commissioners a protest against the allotment of their £90,000 medical benefit surplus. This surplus has accrued because nearly a quarter of a million insured persons would not elect a panel doctor to attend them during illness, and because the authorities entrusted with the fulfilment of the National Health Insurance Act did not distribute those insured persons severally amongst the panel doctors, and did thus disregard Section 15 (2) (*d*) of the Act, which provides for such system as will secure "the distribution amongst, and, so far as practicable, under arrangements made by, the several practitioners whose names are on the lists, of the insured persons who after due notice have failed to make any selection, or who have been refused by the practitioner whom they have selected."

Moreover, according to Section 14 (1) of the Act, it is provided that medical benefit shall be in all cases administered by and through the Insurance Committees and not by the Commissioners.

I am, Sir, yours faithfully,
VIVIAN T. GREENYER,
Oct. 21st, 1914. Chairman of Council of National Medical Union.

DIEPPE AS A MILITARY HOSPITAL BASE.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 3rd there is an article under the above heading to which the Baroness Delaborde-Noguez has just called my attention. She wishes me to say that all the wards at the Casino are thoroughly warmed by stoves, and this I can testify to myself. It is a pity that Dr. Knowsley Sibley was led into the error of supposing it would not be so. Further, a regular staff of nurses are on duty at night at the Casino, and at the College the nuns attend to the wards at night. My work for some weeks past has been at the College, so I can speak from experience. There are now a number of duly qualified nurses at the Dieppe hospitals, and the doctors here greatly appreciate the excellent service they render.

During the time I have been here no wounded have arrived during the night. For the last week we have had none at all, and at least half the beds for wounded have been unoccupied.

I shall esteem it a favour if you will allow me space for this letter. I can quite understand how difficult it must be for anyone paying only a flying visit to this town of hospitals—there are 16 in Dieppe itself—to avoid occasional inaccuracies.

I am, Sir, yours faithfully,
ELIZABETH LE BLOND.
Hotel Chariot d'Or, Dieppe, Oct. 22nd, 1914.

IMPERFECTIONS IN THE CUMBERLAND INFIRMARY.

To the Editor of THE LANCET.

SIR,—Sir Henry Burdett is correct in stating that on the cover of the report of the Cumberland Infirmary for 1913 there may be found a slip of paper which declares "there is accommodation for 150 in-patients," but owing to lack of funds only 102 beds are authorised for occupation. It is not, therefore, incorrect to describe our hospital as a small provincial institution. We could not put up more than 130 patients at most (unless on balconies or open-air spaces), even if our finances permitted. Thirty beds in the disused portion of the infirmary have recently been inspected by the War Office, but only 20 have been considered fit for occupation by wounded or sick.

Sir Henry Burdett tells us that his report on our infirmary is intended to be republished, with some hundred others, as a faithful record of the condition in which he found it in June, 1914. His visit lasted at most two hours, and I cannot regard his report as in any sense a faithful record. In the visitors' book of the infirmary over his signature I find the following:—

> It has been a pleasure to inspect this hospital after 21 years. Since 1892 much has been done to improve the hospital and to add to its efficiency. The working and planning of the new portions of the hospital would be greatly aided if the ward units were made complete by the addition of a suitable airy temporary larder to each ward where the food can be kept, by the provision of a housemaid's cupboard, of patients' clothes cupboards, and other details which are now included in modern hospital construction. The accommodation for the nurses is attractive and good. That for the domestic staff a great improvement on what formerly prevailed, but I should like to see one good room comfortably furnished as a sitting-room for the members of this staff.

When Sir Henry Burdett's faithful record appears will he include this impression? Or will he republish the following remarks from *The Hospital*:—

> Administratively, however, it seemed to us that it has been changed sadly for the worse. .... It was a sad disappointment to find an absence of the old spirit and atmosphere of 20 years before. ...... We are convinced something is radically wrong at this institution.

Satisfied as Sir Henry Burdett appears to have been after his inspection of the Cumberland Infirmary in June, 1914, some unexplained change came over him.

Sir Henry Burdett has condemned our mortuary as having been "erected on a defective plan," and says that every properly organised voluntary hospital has a mortuary chapel or view room, so that "reverence for the dead and due consideration for the living may always be secured." The mortuary in the Cumberland Infirmary was built in 1903, together with a post-mortem room, at a cost of £500, and stands by itself at some distance from any ward. The mortuary or "view room" resembles a small chapel, having an open-timbered roof, a red-tiled floor, with leaded and coloured glass windows at each end. In it four low beds, supplied with fine hemstitched linen, can be found and a little altar table upon which rest a brass cross and vases for flowers placed beneath one window and a "prie Dieu" below the other window. In this "view room" I maintain that all due "reverence for the dead and due consideration for the living" can be secured.

It seems that Sir Henry Burdett cannot understand that in our one clinical room we have all that we require at present and our existing medical staff could not conveniently utilise more than one such room. It may be pointed out to Sir Henry Burdett that if our finances were in a prosperous state we should like to provide an X ray room of three times the size of the one we now have, and that we have no room set apart for the honorary dental surgeon. These and other defects could be remedied, not so much by the possession of the "old spirit and atmosphere" (as Sir Henry Burdett might think) as by the acquisition of increased funds.

I am, Sir, yours faithfully,
Carlisle, Oct. 26th, 1914. H. A. LEDIARD.

⁎⁎ This correspondence must now cease.—ED. L.

THE WAR.

THE ARMY SANITARY COMMITTEE.

The constitution of the Army Sanitary Committee is as follows:—

Brigadier-General F. J. Anderson, R.E.

Arthur Newsholme, M.D., C.B. (Medical Officer, Local Government Board).

Colonel W. H. Horrocks, M.B., B.Sc. (Expert in Sanitation, Army Medical Advisory Board).

Sir Frederick Treves, Bart., G.C.V.O., C.B.

John Robertson, M.D., B.Sc. (Medical Officer of Health, Birmingham).

Henry R. Kenwood, M.B., F.R.S.E. (Civil Expert in Sanitation, Army Medical Advisory Board).

Major C. E. P. Fowler, F.R.C.S., Royal Army Medical Corps (late Officer in Charge, School of Army Sanitation, Aldershot).

General Anderson is the chairman and Mr. Edmond T. Gann will act as secretary.

MENTIONED IN DESPATCHES.

The names of officers in the Royal Army Medical Corps who have been mentioned in Sir John French's despatches under the designation of "General Headquarters Staff, &c.," are given below. From the details supplied in the *Gazette* it was only possible to compile last week a complete list of regimental medical officers and of those specifically grouped together in the list as officers in the Royal Army Medical Corps.

Surgeon-General T. P. Woodhouse, Colonel E. H. L. Lynden-Bell, Colonel T. J. O'Donnell, D.S.O., Colonel H. S. Hickson, Colonel R. Porter, Colonel R. H. S. Sawyer, Brevet-Colonel F. Smith, D.S.O., Lieutenant-Colonel G. H. Barefoot, Lieutenant-Colonel W. W. O. Beveridge, D.S.O., Lieutenant-Colonel F. S. Clark, Lieutenant-Colonel G. Cree, Lieutenant-Colonel C. Dalton (killed), Lieutenant-Colonel J. J. Russell, Major M. H. Babington, Major E. A. Bourke, Major B. B. Burke, Major A. Chopping, Major S. L. Cummings, Major M. H. G. Fell, Major J. V. Forrest, Major J. S. Gallie, Major J. G. MacNaught, Major G. A. Moore, Major C. D. Myles, Major E. Ryan, Major E. B. Steel, Major F. A. Symonds, Major A. H. Waring, Major A. L. A. Webb, Major A. B. Smallman, Captain A. C. Amy, and Captain A. L. Otway.

THE CASUALTY LIST.

THE following names of officers in the Royal Army Medical Corps have appeared in casualty lists since our last issue:—

Wounded: Captain R. E. Porter and Lieutenant H. de C. Dillon.

Missing: Captain B. Johnson and Lieutenant J. L. Jackson.

Captain G. H. Rees, previously reported missing, is now unofficially reported a prisoner of war. Captain D. M. Corbett is unofficially reported a prisoner of war. Cards have been received from Captain S. Field and Lieutenant J. E. Hepper stating that they are prisoners of war at Torgau and are well.

The Secretary of the Admiralty announces that information has been received that Staff Surgeon Louis L. Greig, R.N., of the Royal Naval Division, is a prisoner of war in Germany.

During the operations in Nigeria and the German Cameroons Dr. W. A. Trumper and Dr. J. Lindsay, of the West African Medical Staff, are officially stated to have been captured while attending to the wounded, and Dr. W. S. Clark, also of the West African Medical Staff, was captured at a later date while attending to the wounded, but has since been released.

THE WAR AND THE DRUG SUPPLY.

During the past few weeks the drug market has recovered somewhat from the depression which set in when the war began. Since the note on this subject appeared in THE LANCET of Sept. 19th the medicinal products which have declined in value have exceeded in number those which have advanced, and this is a remarkable fact in view of the existing conditions. Of course, prices on the whole are still greatly above the normal, but it is very satisfactory to know that the advancing tendency which affected so many drugs has been checked. The reasons for this are several. Quite substantial shipments of many of these drugs, of which new supplies were hardly expected, have been arriving at British ports, from which it may be inferred that neutral countries were fairly well supplied with synthetic products and fine chemicals. Then again there is strong evidence that medical practitioners, adopting the suggestion of the Home Office and insurance authorities, have been prescribing whenever practicable and without prejudice to their patients suitable substitutes for German drugs. Thus the consumption of these drugs has been below the normal, while fresh supplies have not been entirely stopped. There are, however, some products which have continued to advance in price. Notable among these are atropine, the extremely high value of which is due to the scarcity of belladonna root; carbolic acid, which is three times its normal price owing to the very heavy demand for this substance, which is required, not only for disinfecting purposes, but for the manufacture of explosives; and corrosive sublimate and other salts of mercury, which have advanced in sympathy with quicksilver. There are some few products, of which menthol is a notable example, which are even lower in price than at normal times, for the reason that supplies which would ordinarily have gone to Germany have been diverted to English ports. Another remarkable feature of the drug market is the comparatively low value of Norwegian cod-liver oil, which in spite of the situation in the North Sea is not substantially higher than that quoted before the war. Opium and its alkaloids, morphine and codeine, are also obtainable at comparatively low figures considering the very heavy demand for them occasioned by the treatment of so many wounded soldiers. The prices are naturally much above the normal in consequence of the disorganisation of the market for Turkish opium, but had it not been for the large supplies of Persian opium that have arrived in London prices would have been excessive.

JOINT RED CROSS COMMITTEE.

On the recommendation of the Duke of Connaught, Grand Prior of the Order, the King, as Sovereign Head, and the Queen, as President of the Ladies' Committee, of the Order of St. John of Jerusalem in England, and Queen Alexandra, as President of the British Red Cross Society, have expressed their approval of the immediate formation of a joint committee of the two organisations, which shall sit throughout the war, to secure coördination and united action in work which is common to both bodies. The committee has been constituted as follows, and communications should be addressed to Room 70, 83 Pall Mall, S.W. :—

Appointed by the Order of St. John of Jerusalem.—Adeline Duchess of Bedford, Lady Perrott, Colonel Sir Herbert Jekyll, K C.M.G. (Chancellor), Colonel Sir Herbert Perrott, Bart. (Secretary-General), the Earl of Plymouth, Lieutenant-Colonel Sir Richard Carnac Temple, Bart., Sir John Hewett, G.C.S.I., and the Right Hon. Sir Claude Macdonald, G.C.M.G.

Appointed by the British Red Cross Society.—The Marchioness of Lansdowne, Georgina Countess of Dudley, Sir William Edmund Garstin, G.C.M.G., Sir Robert Arundel Hudson (chairman of Finance Committee), Sir Walter Roper Lawrence, G.C.I.E., Mr. Edward A. Ridsdale, the Hon. Arthur L. Stanley, M.V.O., M.P. (chairman of the Executive Committee), and Sir Frederick Treves, Bart., G.C.V.O.

NEW WAR OFFICE APPOINTMENT.

Colonel Michael W. H. Russell, R.A.M.C., has been appointed Deputy Director-General of the Army Medical Service, and to be temporary surgeon-general, in succession to Surgeon-General W. G. Macpherson, A.M.S., C.M.G., K.H.P.

THE CONTINENTAL MEDICAL PRESS AND THE WAR.

Nothing is more suggestive of the intense preoccupation of France in the struggle for national survival in which she is engaged than the state in which the *Presse Médicale* now appears. The first number to betray the changed state of affairs was published on August 12th. It begins with a paragraph explaining that owing to the early mobilisation of its editorial secretaries, and also to the events now filling the mind of every Frenchman, certain changes have been necessary. In a most stirring article M. Helme outlines the policy of the journal as one of assistance to those who are not at the front and yet wish with their whole heart to serve their country. For the consolation of such he quotes with approval the words of a surgeon just dead to the effect that "every battlefield is good to the man who desires to do his duty." All the articles and paragraphs in this and subsequent numbers deal exclusively with the war. There are several admirable lectures by Edmond Delorme, Medical Inspector-General of the French Army, and others on military surgery. Other paragraphs deal with the organisation of civil practice, of relief work, and so on. There are also directions for the execution of anti-typhoid vaccination. Details of Red Cross arrangements are given, and a very interesting column is devoted to replies to correspondents. An article from the *New York Herald* is quoted at length in which the allegations of the Germans with regard to dum-dum bullets are dealt with, the conclusion arrived at being that it is impossible to deduce from the mere appearances of wounds that such bullets have been used, and that in fact nothing but the discovery of unused dum-dum bullets can be held to prove the charge that has been advanced against the Allies. In this connexion may be quoted the opinion said to have been expressed by a German surgeon since the outbreak of war, and reproduced from one of the German journals in an American medical weekly, to the effect that the rifle bullet of the French army inflicts a clean and relatively humane wound. It is impossible to read the *Presse Médicale* without a sense of admiration for the passion with which the French nation has undertaken the task thrust upon it by the unscrupulous ambitions of the enemy. The German medical weeklies are still appearing. From these we learn that the health of the army is regarded as satisfactory, and that the medical organisation is thought to be equal to the heavy strain which is already being thrown upon it. The papers are reduced in bulk, and deal largely but not exclusively with military subjects. One reference to a British journal, the *Western Medical News*, published in Saskatchewan, may be permitted. Like the French journal alluded to, this is largely given up to war items. The editorial notes quote the words with which Professor Depage, of Brussels, opened the Fourth International Surgical Congress, to the effect that "it is the privilege of little Belgium to offer a meeting-place to the learned men of all nationalities, covered by Europe herself with the shield of peace and liberty." When these words were spoken few thought that within a few weeks one of the guarantors of that peace and liberty would be devoting all her energies to a ruthless campaign of violence and tyranny in the very land she had solemnly undertaken to protect.

OBITUARY OF THE WAR.

GEORGE CHARLES CUMBERLAND ROSS, M.B., B.CH. T.C.D.,

STAFF SURGEON, ROYAL NAVY.

Dublin students of the "nineties" will have learned with great regret that Staff Surgeon George C. Ross, R.N., is supposed to have lost his life in the disaster to H.M.S. *Hawke* on Oct. 15th in the North Sea. Ross was a student of Trinity College and the Richmond Hospital, and became qualified in 1899, graduating M.B., B.Ch., and B.A.O. of the University. He had obtained his B.A. degree two years previously. During his college career he nearly lost his life by a sailing accident in Dublin Bay. He was the eldest son of Surgeon-Colonel George Cumberland Ross, late I.M.S., with whom much sympathy is felt. He entered the navy as surgeon in 1901 and was promoted to be staff surgeon in February, 1909. He joined the *Hawke* on August 1st last, and there seems to be now no hope that he and his two medical colleagues, Surgeon G. W. M. Custance and Temporary Surgeon J. H. D. Watson, have survived.

WILLIAM ORMSBY WYNDHAM BALL, M.B., CH.B. T.C.D.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant W. O. W. Ball, who was killed on Sept. 26th during the battle of the Aisne, was born on Sept. 27th, 1889, at Palmerston Park, Dublin. He was the younger son of the late Henry Wyndham Ball. From St. Andrew's College, Dublin, he proceeded in 1907 to the University of Dublin, graduating B.A. in 1910 and M.B., Ch.B., B.A.O. in 1912. He had a distinguished career as a student in the School of Physic of Trinity College, and acted as resident pupil at Sir Patrick Dun's Hospital during his final year. In 1912 he obtained the L.M. diploma of the Rotunda Hospital. He was one of the first members of the medical unit of the Dublin University Officers Training Corps, which was established four years ago, and which has sent so many University men to the front in the present crisis. Lieutenant Ball entered the Royal Army Medical Corps in January, 1913, and before the outbreak of war was stationed at Longmoor. He was killed on the eve of his twenty-fifth birthday while in the act of tending a wounded soldier. During the great retreat from Mons towards Paris he had already had several narrow escapes. Once whilst he was dismounted and dressing a wounded man his horse was shot; on another day a bullet passed through his water-bottle; while on a third occasion, when in charge of a stretcher party, a shell burst not 20 yards away on the spot where he had been standing a minute before. He was also hit by a spent bullet and several times by fragments of shells, but was uninjured. Whilst a student at Trinity College Ball was a noted hockey player and played for Ireland in six international matches during 1909 and 1910.

JOHN CROCKET, M.D., CH.B. EDIN.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant John Crocket, who was killed in action with the Expeditionary Force at the age of 28, was the only son of Mr. William Crocket, of Balmaghie, Headmaster of Sciennes School, Edinburgh, and a nephew of the well-known Scottish novelist. He was educated at Watson's College, Edinburgh, and graduated M.B., Ch.B., at the University of Edinburgh in 1908. After graduation he acted as resident house surgeon at the Edinburgh Royal Infirmary, resident medical officer at Chalmer's Hospital, and house surgeon at the Royal Hospital for Sick Children, Edinburgh. He obtained his M.D. degree this year, the title of his successful graduation thesis being "The Noguchi Luetin Reaction." He received his commission as Lieutenant in the Royal Army Medical Corps in January, 1913, and was recently stationed at Edinburgh before leaving for the front. Lieutenant Crocket was a man of considerable force of character and individuality. During his student days he took a leading part in the affairs of the Edinburgh University and Dumfries and Galloway Society, and he was an enthusiastic golfer and lawn-tennis player.

THE BRITISH RED CROSS SOCIETY.—The summary of work for the week ending Oct. 28th, shows that the number of hospitals accepted by the War Office to date is 247, containing beds for 8077, including 1597 beds accepted during the past week, and distributed among the Army Commands as follows:—London, 606; Eastern, 2678; Irish, 189; Southern, 1834; Northern, 1270; Aldershot, 609; and Western, 891. A number of Red Cross Voluntary Aid Detachments are being utilised in connexion with these hospitals.

Sir Robert Borwick having generously promised £2000 a year, to be paid quarterly during the war, for the maintenance of sick and wounded Colonial officers in nursing homes, arrangements have been completed with the nursing homes of Miss Lancaster, 29, Wimpole-street, W., and Miss Pollock, 50, Weymouth-street, W., for the reception and treatment of Colonial officers. The surgical and medical staffs have now been completed, and the following is a roll of the names of those who have generously given their services in connexion with the above nursing homes:—Mr. Charters Symonds, Mr. C. A. Ballance, Sir Seymour Sharkey, Dr. H. P. Hawkins, Mr. Harold Gardiner, Mr. J. F. Jennings, and Dr. J. Brunton Blaikie; Dr. F. E. Shipway, Dr. Z. Mennell, and Dr. Arthur Bevan are the anæsthetists; Mr. A. D. Reid the radiographer; and Mr. J. Dudley Benjafield the bacteriologist.

The British Red Cross Hospital at Netley is gradually getting into working order as the contractors complete the huts. 100 beds are now available for patients, and a certain number of sick and wounded were admitted on Oct. 26th.

CHADWICK PUBLIC LECTURES: WAR PROGRAMME.—The trustees of the Chadwick Public Lectures announce the following programme for the coming three months. On Saturdays, Nov. 14th, 21st, and 28th, at 3 P.M., Dr. A. T. Nankivell will lecture at Bedford College, Regent's Park, on Camp, Ship, and Hospital Hygiene. On Fridays, Dec. 4th and 11th, at 8.15 P.M., Sir Ronald Ross, K.C.B., will lecture at the London School of Economics, Clare Market, Kingsway, on Government and Military Sanitation in the Tropics. On Fridays, Jan. 15th, 22nd, and 29th, 1915, at 5.15 P.M., Dr. F. M. Sandwith, Gresham professor of physic, will lecture at the Royal Society of Arts, John-street, Adelphi, on War and Disease. Admission will be free to all the lectures. With the sanction of the Medical Director-General of the Navy and by arrangement with the Surgeons-General of the respective ports a course of three Chadwick lectures on Naval Hygiene—(1) the Progress of Naval Hygiene and its Effects on the Health of the Navy; (2) the Health of the Ship; and (3) the Health of the Sailor—will be given by Professor W. J. Simpson, C.M.G., M.D., in the Mayor's Room, Town Hall, Portsmouth, on Fridays, Nov. 27th and Dec. 4th and 11th, at 9 P.M., and in the R.N. Hospital, Plymouth, on Saturdays, Nov. 28th and Dec. 5th and 12th. Further particulars of these and other Chadwick lectures may be obtained from the secretary at the offices of the Chadwick Trust, 8, Dartmouth-street, Westminster.

THE HISTORICAL MEDICAL MUSEUM: A WAR EXHIBIT.—A special exhibit of interesting objects and relics associated with naval and military surgery, nursing, and ambulance is being arranged at the Wellcome Historical Medical Museum in Wigmore-street. It will include miniatures, portraits, prints, autograph letters, commissions, and relics of famous naval and military surgeons, surgical instruments and appliances used in naval and military surgery in bygone times, also medical and surgical chests, cases and cabinets, &c., used in war time. Pictures, prints, and drawings of field ambulance work, military hospitals, appliances, and equipments will also be included. The curator would be glad to hear from medical practitioners who may be willing to lend relics, instruments, or objects of a similar character. Any objects lent will be treated with the greatest care and insured against loss or damage. Particulars and descriptions of loans should be sent as early as possible, addressed to the Curator, the Wellcome Historical Medical Museum, 54A, Wigmore-street, London, W.

THE WORK OF THE VOLUNTARY AID DETACHMENTS IN KENT.—A correspondent writes: "The organisation of the V.A. Detachments in Kent has been put to the test and stood the strain very well. On Oct. 14th at midnight, for example, certain detachments were warned that 4000 Belgian wounded had been landed at Folkestone. The following relates to the work at a certain small town in Kent where 50 cases were sent to a large empty country house. The wounded arrived at 10 A.M., notice of their arrival being given only half an hour in advance. Order for 'mobilisation' had been received at midnight; the house was then quite empty, but clean. By 9 A.M. all beds were ready and equipment assembled for clothing, feeding, and dressing wounds. The resident medical officer had been fetched by car from an adjacent county and was on duty at 6 A.M. The nurses, cooks, and male orderlies were in attendance, and the conveyance of wounded from the station was carried out by one ambulance for three stretcher cases and a number of cars. A receiving tent had been pitched, equipped with a bath, and by noon the weary, exhausted men were all in bed, washed and fed, and all wounds were dressed by 8 P.M. The wounded had been mostly cleared from base hospitals in Ostend, Ghent, and Antwerp, and none of them had been attended for three or four days. The injuries comprised several severe perforating rifle wounds of the elbow joint, and various compound fractures of the lower arm and of the carpus and metacarpus. There was a case of rifle wound perforating the base of the skull from a point anterior to the left pinna to a point on the opposite side of the nose; this injury had produced severe pain in the branches of the third nerve and acute delirium, probably the result of pain, exhaustion, and mental distress, as there were no signs of meningitis. A number of minor wounds and cases of subacute rheumatism brought the total to 54. One severe case of tetanus manifested itself within 24 hours in a very bad septic wound of the elbow-joint. Intravenous injection of antitetanus serum was at once made, followed by large rectal injections of a mixture of normal saline and sulphate of magnesia, but the case was very acute and terminated fatally within two days. Considering that the handling of such a large body of patients was performed by amateurs under the lead of one trained nurse the organisation deserves great credit. And I learn that the same success has been made in the other detachments of the county."

Transport of the Wounded.—In three days, Oct. 24th to 26th, a number of hospital ships arrived at Southampton. They brought about 2000 invalid and wounded troops, who were sent to hospitals in various parts of the country. Among the wounded were a number of Belgians and Germans. Thoughtful provision is shown to the wounded by the distribution, as the trains are leaving the Southampton Docks for the various hospital centres, of cigarettes, tobacco and pipes, and bars of chocolate, a kindness which is very much appreciated.

Wounded Soldiers in Ireland.—On Monday last the Bibby liner *Oxfordshire*, fitted as a hospital ship, reached Queenstown from Boulogne, carrying some 26 wounded officers and 700 wounded non-commissioned officers and men. They belonged to some 21 different regiments, including the Connaught Rangers, the Leinsters, the Royal Irish, the Munsters, and the Inniskillings. Of the patients 326 were sent to Dublin, 16 to Youghal, 20 to Waterford, 10 to Buttevant, 50 to Limerick, 25 to Fermoy, and 250 to Cork. Special ambulance trains ran to Cork and Dublin.

The Forth Naval Hospital. — A fully equipped emergency naval hospital was offered soon after the outbreak of war by an anonymous donor and has been accepted by Queen Mary and Princess Christian. The site selected for the building is in close proximity to the Royal Naval Hospital at South Queensferry, and within the remarkably short period of some eight weeks the extensive range of wood and corrugated iron buildings was completed. The building comprises a large central administrative block of eight rooms for the accommodation of the surgical and medical staff. From the centre of each side and from three of the angles of this central building radiate the wards, messroom, kitchen, and operating theatre. The operating theatre has been constructed according to the latest requirements, and attached to it are a dispensary, anæsthetist's room, sterilising room, and a dark room for X ray work. There are four wards. The hospital building also comprise a detached commodious set of apartments for the accommodation of the staff, an electric light installation, and an ambulance shed.

Royal Medical Benevolent Fund and the War.—In consequence of the war the College Council Club of the Royal College of Surgeons decided not to hold their usual dinner this quarter, but instead a cheque of 30 guineas has been contributed to the Royal Medical Benevolent Fund, an example which should be largely followed by those who had intended to hold dinners and festivals of the kind. The medical profession will certainly be hit hard by the war in many ways, and already special demands upon the fund are being made, of which the following is a specimen. A young doctor, only seven years in practice and recently married, having volunteered for the war, was killed in the field within the first week, leaving a widow and two children in great temporary distress. This is but an example of many distressing cases, and the fund will find it difficult to deal with them as liberally as it would desire without special help and generous support.

The Second Southern General Hospital.—A correspondent writes:—"Ever since the first batch of wounded from the battlefields of Mons, Cambrai, and so on, were admitted to this hospital early in September the staff have been kept busy. At the present time there are about 600 patients, or more if the convalescent branch at Bishop's Knoll be included. The largest class is composed of wounded and sick from the Expeditionary Force. The results of treatment have been gratifying on the whole, and so far no patient has died from wounds in the hospital. Practically the only mortality, indeed, has been due to pneumonia occurring among the recruits. There are 200 Belgian soldiers, many of whom had been moved hastily from one hospital to another in their own country. The great majority of these men are doing well, though several are severely wounded. Almost all of them have heard nothing of their families for weeks, and do not even know whether their wives and children are still alive. As has been already explained, it has been unavoidably necessary to divide the hospital into two parts. The smaller city division is full, but the larger Southmead portion, installed in the new premises of a workhouse infirmary, seems to be susceptible of almost indefinite expansion."

Professional Classes War Relief Council.—As we go to press we are asked to draw the attention of our readers to an organisation which has been formed with the above title for the practical assistance of members of the professional class who are in distress through the stringent conditions brought about by the war. The object of the council is to seek out such cases, and by advice and, where necessary, by assistance to render what help is possible. The council contains representatives from the chief professional institutions and from the societies which already exist for the organisation of relief, and its object is to coördinate, without any attempt at controlling, the activities of these institutions. In the directions of education of children, training for employment at home or in the colonies, maternity assistance, and the provision of temporary employment, it is hoped that the council through its special committees will be able to deal with each family as a unit, and thus help the dependents of professional men and women in a more effective and economical way than would be possible by mere grants of money. The medical members of the council, whose offices are at 13 and 14, Prince's-gate, London, S.W., are Sir John Tweedy and Dr. Samuel West, president and treasurer of the Royal Medical Benevolent Fund, and Dr. Mary Scharlieb, and further information as to the objects and methods of the council will be furnished on application to the honorary secretaries.

The Welsh Military Hospital.—We have so far not described this base hospital, the Welsh Hospital, which was inaugurated at a largely attended public meeting held at Cardiff on August 11th, under the presidency of the Lord Mayor (Mr. J. Robinson, M.R C.S., J.P.). Through the medium of the British Red Cross Society it was offered, on behalf of the Principality, to the War Office, for service with the Expeditionary Force, by H.R.H. the Prince of Wales. The offer was accepted, and it was requested that the hospital should be located in the first place at Netley, to go overseas later when required. The Welsh Hospital is therefore now situated on the recreation ground of the Royal Victoria Hospital—a very healthy spot. It was ready to receive patients on Oct. 26th. The buildings of the hospital are of wood and galvanised iron and are portable. The honorary architects are Messrs. E. T. and E. Stanley Hall, of London, the architects of the Manchester Royal Infirmary and the Welsh National Memorial.

The hospital has accommodation for 104 patients in four ward pavilions, each containing a 24-bedded ward, two single-bedded wards, and the usual accessory rooms. The other pavilions are: Entrance (in which is included post-mortem room and mortuary), administrative, operating theatre, pathology, X rays, and dispensing, mess rooms, kitchen and stores, laundry, staff quarters. The different pavilions are linked up by an open corridor. The operating theatre has been specially constructed. Heating is by gas and by anthracite stoves, lighting by electricity, hot water-supply from "calefonts," and the sanitary fittings connect up with an adjacent drain.

The total staff numbers 48. The commanding officer and senior surgeon is Lieutenant-Colonel A. W. Sheen, R.A.M.C.(T.F.), surgeon to King Edward VII. Hospital, Cardiff. The other medical officers are Mr. Fergus Armstrong, M.D. Edin., F.R.C.S. Edin., Mr. T. Garfield Evans, M.D. Lond., Mr. Sydney J. Rowlands, M.D. Liverp., and Mr. Bernard G. Klein, M.D. Oxon. The quartermaster is Mr. E. J. August, and all these officers have been given temporary commissions in the Royal Army Medical Corps. Four senior medical students are engaged as dressers, and the rest of the male staff consists of a sergeant-major, two sergeants, and 12 orderlies. The matron is Miss M. Martin, who served with the Welsh Hospital in the South African War, and there are 12 nursing sisters, a housekeeper, and a domestic staff. The Earl of Plymouth is the President, the Lord Mayor of Cardiff chairman of the executive committee, and Mr. C. Hope the honorary general secretary.

The response to the appeal for funds signed by the Lord Mayor of Cardiff and Sir W. J. Thomas, honorary treasurer of the hospital, was immediate and enthusiastic, over £10,000 being subscribed in a week. The sum asked for is £25,000, and this amount has nearly been reached. £250 is regarded as endowing a bed to be named after the donor, and there are already 62 such endowed beds. All Wales has taken part in the movement, and many beds are endowed from North Wales. Sir William James Thomas endowed ten beds, and Mr. David Davies, of Llandinam, four beds; the Earl of Plymouth and the Marquis of Bute each two beds. A ladies' committee, under the chairmanship of the Lady Mayoress of Cardiff, have obtained garments and linen for the hospital estimated to be worth £1000. When required the hospital is ready to pack up and move as far as its furniture and equipments are concerned at short notice. The buildings will take longer to move, and perhaps existing buildings will be occupied in the new location. During its sojourn at Netley the staff will be further trained in drill, discipline, and duties in connexion with a military hospital under an experienced commanding officer, so as to render the hospital thoroughly fitted for any work it may be called upon to do.

GERMAN MEDICAL CASUALTIES.—The first German official casualty list of military surgeons is stated to include the names of 74 killed, 37 wounded, 13 missing, 3 prisoners, and 8 died from sickness. According to a German periodical the losses of the German military medical staff during the war of 1870 were 66 in all, of whom 9 were killed outright, 2 died of wounds, and 55 died from disease. The Austrian medical corps are stated to have lost during the present campaign 8 killed, 25 wounded, and 1 missing, while 22 are suffering from illness of various kinds. A newspaper correspondent in Copenhagen announces that already 118 military surgeons have been decorated with the German Iron Cross.

Mr. Robert Fox-Symons has been added to the Anglo-French hospital committee which was formed recently for the purpose of coördinating British offers of help for the French sick and wounded. Since Mr. G. H. Makins's departure for the front as consulting surgeon to the Forces Mr. Fox-Symons has been in charge of the department of the British Red Cross Society which deals with auxiliary home hospital accommodation.

THE NATIONAL INSURANCE ACT.

LOCAL MEDICAL COMMITTEE FOR THE COUNTY OF LONDON.—At a meeting of this Committee on Oct. 21st, at the offices of the Metropolitan Asylums Board, Dr. James Galloway in the chair, a report was considered from a special subcommittee appointed to consider and report upon the constitution, powers, duties, and finance of the Committee, and recommendations were adopted that the interests of the personnel of the Local Medical and Panel Committees for the County of London should be identical; that until it is possible to secure that the personnel of the two committees is identical the Local Medical Committee should offer advice on matters connected with the administration of the benefits of insured persons only when that advice is sought; that the Local Medical Committee should exercise their powers and duties in the closest coöperation with the Panel Committee; and that an executive committee be appointed to consider and report from time to time as may be required upon all matters referred to the Local Medical Committee. The executive committee appointed will consist of Dr. James Galloway (chairman), Dr. B. A. Richmond (secretary), together with Dr. J. A. Butler, Dr. H. J. Cardale, Mr. J. V. C. Denning, Dr. Mina Dobbie, Mr. W. McAdam Eccles, Dr. M. Greenwood, Dr. W. Kingdon, Dr. J. T. Richards, Mr. J. J. Scanlan, and Dr. A. G. Southcombe. With regard to the proposed federation of Local Medical and Panel Committees, it was resolved that the Committee were unable to accept membership of the federation under its constitution as at present drafted.

DUPLICATION IN INDEX REGISTERS.—At a recent meeting the Sheffield Insurance Committee was informed that the difference between the number of insured persons shown on the index registers of the societies for Sheffield and the number estimated by the Commissioners as being insured there was 24,000, the figures in the former case being 172,000 and in the latter 148,000. It was pointed out that this might mean a considerable shortage in the money to be applied to the payment of medical benefit. The Commissioners had intimated that the number shown by the index registers throughout the country was greatly in excess of the number of persons insured, and that they were only prepared to pay upon the number insured. Members of the Sheffield committee strongly protested against deduction being made from the sum claimed by Sheffield upon any principle involving the taking of an average throughout the country, on the ground that records in Sheffield were carefully kept and checked, and that the committee was not prepared to suffer for inaccuracies allowed by other committees. It was decided that the finance and panel committees should confer on the subject.

PROPOSAL TO MAKE TUBERCULOSIS THE CARE OF THE STATE.—At the National Conference of Friendly Societies concluded recently at Norwich a proposal of the executive committee was discussed, and a resolution in its favour carried, to the effect that sanatorium benefit should be eliminated from the Insurance Act and that the State should provide for all patients suffering from tuberculosis. On behalf of Scotland it was urged that the Scottish local authorities had created their machinery and would object to it being "scrapped," and it was also argued that the organisation in Wales for combating consumption was such that Wales should be excluded from the resolution. The amendments proposed were, however, lost. A resolution was also carried at the conference calling upon the Government to make a grant of half-a-crown per member per annum towards the cost of providing medical attendance and medicine for members of Friendly Societies who at the passing of the Insurance Act were prevented from becoming insured by reason of age or ill-health.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—J. A. A. Boddy (Sections I. and II.), Manchester M. M. Burt (Sections I. and II.), Birmingham; P. H. Burton (Sections I. and II.), London Hospital; W. Brown (Section I.), Oxford and King's College Hospital; C. H. Fischel (Section I.), Middlesex Hospital; and J. Stephenson (Sections I. and II.), Guy's Hospital.

Medicine.—W. Brown (Section II.), Oxford and King's College Hospital; H. H. Fairfax (Section I.), Charing Cross Hospital; C. H. Fischel (Section II.), Middlesex Hospital; N. W. Rawlings (Section I.) and G. Robinson (Sections I. and II.), Manchester; J. Stephenson (Sections I. and II.), Guy's Hospital; W. C. S. Wood (Sections I. and II.), King's College Hospital; and A. K. S. Wyborn (Section II.), Middlesex Hospital.

Forensic Medicine.—W. Andrew, King's College Hospital; C. E. Clarke, Bombay; A. J. Fradersdorff, Guy's Hospital; N. Hoffmeister, Middlesex Hospital; G. Robinson, Manchester; J. Stephenson, Guy's Hospital; and W. C. S. Wood, King's College Hospital.

Midwifery.—A. U. L. Bennet, Royal Free Hospital and Dublin; M. M. Burt, Birmingham; C. S. Dodson, Cambridge and University College Hospital; J. Stephenson, Guy's Hospital; and W. C. S. Wood, King's College Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: P. H. Burton and J. Stephenson.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The quarterly examinations of the above Board, held in Edinburgh, were concluded on Oct. 26th, with the following results:—

First Examination.—Mahmoud Abdel Kader Mofreh, William Bruce Lawson, Archibald Buchanan MacDougall, Ernest Ebenezer Bronstorph, and Hassan Amin Madwar, and two passed in Physics and three in Biology.

Second Examination.—Jackson Baird Minford, Nicholas Johannes Laubscher, Henry Morley, Robert Woodside, Frank Jones, John Lavens West, Paul Vertannes, William Ulie Desmond Longford, Clifford Pullan, and George Murray Shaw Lindsay, and three passed in Anatomy and five in Physiology.

Third Examination.—Elliot Paxton Dewar, Gulabrai Teckchand Makhijani, Yeshwant Narayan Kadam, Charles Evelyn Meryon, John Robert Beith Robb, William Graham Bowie, Maurice Andrew

White, and Alfred Edwin Elliott, and three passed in Materia Medica.

Final Examination.—Allan Beresford Hawkins, British West Indies; Florence Winifred Heyworth, Liverpool; Norman Hamilton Brewster, British West Indies; William Henry O'Grady, co. Mayo; John Ramsay Fleming, Airdrie; Gerald Christopher Stanley Perera, Ceylon; William Clarke Fraser, Dundee; Arthur Edwin James, Auckland, New Zealand; Leonard Owen Weinman, Colombo; Arthur Alexander Murison, Dumbarton; John Martin, Glasgow; Gwilym Llewelyn Pierce, Llangollen; William Smith O'Loughlin, Limerick; and Khusru Roostamji Mehta, Calcutta; and 4 passed in Medicine, 10 in Surgery, 12 in Midwifery, and 11 in Medical Jurisprudence. (These candidates received their diplomas.)

University of Glasgow.—In the Third Professional Examination (Old or New Ordinance) and Fourth Professional Examination (New Ordinance) the following have passed in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

William Dick Allan (P.), William Baird (P.), Joseph Edward Bannen (P.), Thomas Blackwood (P.), Archibald Campbell Brown (P.), Henry Drummond Brown (P.), John Alexander Buchanan (P.), Stuart Ernest Armstrong Buckley (P.), Duncan Cameron (P.), David Campbell, M.A., B.Sc. (P.), Dugald Stewart Campbell (M.), William Campbell (P., M.), Moses Wolffe Cantor, B.Sc. (P., M.), Joseph Chalmers (P.), David Clyde (P.), William Kerr Connell (P.), Alexander Findlay Cook (P.), Archibald Shankland Cook (P.), Walter Gow Cook (P.), John Norman Cruickshank (P.), John Freeland Cunningham, M.A. (M.), Robert Cunningham (P.), Alexander Dick (M.), Ronald Stevenson Dickie (P., M.), William Donald (M.), Samuel Norman Dykes (P.), Lewis Livingstone Fotheringham (P.), Matthew Mair Frew (P.), David Gould Gardiner (M.), Robert Stuart Gibson, B.Sc. (M.), Norman William Gilchrist (M.), Samuel John Henderson (P.), William Yuill Jamieson (P., M.), Stewart Johnstone (P.), George Kirkhope (P.), John Crawford Knox, B.Sc. (M.), Robert Kyle (P., M), James Alexander Leiper (P.), Robert Lindsay, M.A. (P.), Hugh Lawrence M'Cormick (P., M.), Donald Kerr MacDougall (P.), David M'Farlane (M.), James Wallace Macfarlane (P.), John Mandeville Macfie (M.), John MacInnes (P.), James Murdoch MacKay (P.), Keith Stuart Macky (P.), Alexander Fisher M'Millan (P.), David M'Neill (P., M.), Eric John MacPhail (P.), Noah Morris, B.Sc. (P., M.), Alexander Morton (P.), John Hughes Murray (M.), William O'Brien (P.), Arthur William Panton (P.), Thomas Smith Paterson (M.), James Herbert Paul, M.A., B.Sc. (P., M.), William James Poole (M.), William Burns Primrose (M.), John King Rennie B.Sc. (M.), James Richardson (P.), Robert Rodger (P.), George William Ronaldson (P.), Alexander Forbes Ross (P.), Kenneth M'Alpin Ross (P.), Angus M'Alpine Scott (P.), William Frederick Shanks (M.), James Steel (P.), John Steele (P.), Abraham Raphael Steinberg (P.), William Mitchell Stewart (P.), John Stirling, B.Sc. (M.), George Carson Swanson (P.), Robert Taylor (P.), Herbert Watt Torrance (P.), John Dalglish Watson (P., M.), William James Cunningham Watt (P.), and Robert James Wilson (P., M.).

Women.—Christina Blair Buchanan (P.), Maud Christine Cairney (P.), Ann Kelly Cormack (M.), Winifred Jane Crawford (P.), Jane Beattie Davidson (P.), Jessie Crawford Gilchrist (P.), Jean Lawrie Hamilton (P.), Janet Fraser Henderson (M.), Helen Isobel Winifred Kerr (P.), Dorothy M'Cubbin (P., M.), Mary Ann MacLennan MacLean (P.), Effie Cowan M'Vie (P., M), Elizabeth Stewart Martin (P.), Margaret Kay Mitchell (P.), Janey Lamond Munro (M.), Helen Young Murdoch, M.A. (P.), Mary Helen Routledge (P.), Mary Scott (P.), Mary Ishbel Sinclair (M.), Jane Stalker (P), Alison Edgar Wilson (P.), and Marion Baillie Darling Wilson (P.).

Dr. Richard Whittington was on Oct. 24th elected a member of the Brighton town council.

A Medical Lord Mayor.—Dr. J. G. Gordon-Munn has been selected as the new Lord Mayor of Norwich for the coming year.

University of Cambridge. — The Special Board for Medicine have elected Professor Howard Marsh, Master of Downing College, as their representative upon the General Board of Studies in the University. Mr. W. B. Hardy, F.R.S., tutor of Gonville and Caius College, has been appointed a manager of the Gerstenberg studentship in moral philosophy and metaphysics, in place of the late Dr. W. H. Gaskell. Mr. J. E. Purvis, St. John's College, has been re-appointed University lecturer in chemistry and physics in their application to hygiene and preventive medicine.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Addison, Kate, M.B., B.S. Lond., has been appointed Clinical Assistant in the Skin Department at the Royal Free Hospital.

Barnes, H. W., M.B. Cantab., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Acting Medical Officer of Health and School Medical Officer for Luton.

Blair, Miss A., M.B., B.S., has been appointed Senior Clinical Assistant in the Gynæcological Department at the Royal Free Hospital.

Blakeway, H., F.R.C.S. Eng., M.S. Lond., has been appointed Acting Assistant Surgeon to the Royal Free Hospital.

Gardiner, Harold, M.B., B.S. Lond., F.R.C.S., has been appointed Acting Assistant Surgeon to the Royal Free Hospital.

Garstang, W., M.B., Ch.B. Vict., has been appointed Medical Officer of Health to the Hucknall Urban District Council.

Lloyd, Muriel, M.B., B.S. Lond., has been appointed Resident House Physician at the Royal Free Hospital.

Macpherson, Louis, M.D. Edin., has been appointed Tuberculosis Officer for the Counties of Mid- and West Lothian and Peeblesshire.

McCormick, J., M.B., B.Ch. N.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Buncrana District of the county of Donegal.

Moon, G. B., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Second Assistant Medical Officer at the Surrey County Asylum Netherne.

O'Reilly, E., M.B., B.S. R U.I., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Ballyhaise District of the county of Cavan.

Paterson, Miss M. R., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at the Royal Free Hospital.

Pillman, Miss M. E. C., M.R.C.S., L.R.C.P., has been appointed Resident House Surgeon at the Royal Free Hospital.

Powell, Miss E. M., M.R.C.S., L.R.C.P., has been appointed Resident House Surgeon at the Royal Free Hospital.

Salisbury, Walter, M.B., B.S. Lond., has been appointed Resident Medical Officer at Queen Charlotte's Lying-in Hospital.

Smith, W. Maule, M.D. Edin., M.R C.P. Edin., has been appointed Medical Superintendent to the West Bromwich and Walsall Joint Unions.

Stuart, J., L A.H. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Belturbet District of the county of Cavan.

Vinter, C. H. S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Framlingham District of the county of Suffolk.

Walsh, Harold V., M.B , B.Ch. Belf., has been appointed Assistant Resident Medical Officer at Queen Charlotte's Lying-in Hospital.

West, T. Ruddock, M.B., B.S. R.U.I., has been appointed Assistant School Medical Officer and Assistant Medical Officer of Health of Norwich.

Whitney, Cyril U., L.R.C.P. Lond., M.R.C.S., has been appointed Deputy Medical Officer of Health of Maldon, Essex.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bethnal Green Infirmary, Cambridge-road, N.E.—Two Assistant Medical Officers. Salary at rate of £200 per annum, with apartments, board, and washing.

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £100 per annum, with board and laundry.

Birmingham Corporation.—Female Medical Officer for Infant Consultation Work. Salary £300 per annum.

Birmingham General Hospital.—House Governor and Secretary. Salary £500 per annum.

Birmingham Union.—Dudley-road Infirmary: Third Assistant Medical Officer and Fourth Assistant Medical Officer. Salary at rate of £170 and £160 per annum respectively. Erdington Infirmary and Cottage Homes: Assistant Medical Officer. Salary at rate of £200 per annum. Selly Oak Infirmary: Assistant Medical Officer. Salary at rate of £180 per annum. Apartments, rations, laundry, and attendance in each case.

Bolton Infirmary and Dispensary.—Second House Surgeon. Salary £120 per annum, with apartments, board, and attendance.

Bootle, Corporation Hospital for Infectious Diseases.—Resident Medical Officer, unmarried. Salary £250 per annum, with board, washing, and apartments.

Bournemouth, Royal Victoria and West Hants Hospital.—House Surgeon, unmarried, for six months. Salary £100 per annum, with board, lodging and washing.

Bradford Royal Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing.

Brentwood Asylum, Brentwood, Essex.—Locum Tenens Assistant Medical Officer. Salary £5 5s. per week, with board, attendance, lodging, and washing.

Bristol City Asylum, Fishponds.—Second Assistant Medical Officer, unmarried. Salary £250 per annum, with apartments, board, washing, and attendance.

Bromsgrove, Worcestershire Asylum.—Deputy Medical Superintendent and Second Assistant Medical Officer. Salary £300 and £225 per annum respectively, with apartments, board, washing, and attendance.

Burslem, Haywood Hospital.—Female Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.

Canterbury, Kent County Asylum, Chartham.—Junior Assistant Third Medical Officer, unmarried. Salary £250 per annum, with quarters, board, washing, &c.

Canterbury Mental Hospital.—Assistant Medical Officer. Salary £250 per annum, with board, lodging, laundry, &c.

Carshalton, Surrey, Queen Mary's Hospital for Children.—Assistant Medical Officers. Salary at rate of £250 per annum, with board, lodging, and washing.

Chelsea Hospital for Women, Fulham-road, S.W.—House Surgeon for six months. Salary £80 per annum.

Cheshire Education Committee.—Fourth Assistant to the Chief School Medical Officer. Salary £350 per annum.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing.

City of Westminster Union Infirmary, Fulham-road, S.W.—Second Assistant Medical Officer and Third Assistant Medical Officer. Salaries £160 and £140 per annum respectively, with board, residence, and washing.

County of London.—Lecturers in First Aid, Home Nursing, Health, and Infant Care. Salary £1 1s. a lecture.

DERBY, DERBYSHIRE COUNTY COUNCIL.—Assistant Tuberculosis Officer. Salary £400 per annum.

DOUGLAS, ISLE OF MAN, NOBLE'S HOSPITAL.—Resident House Surgeon, unmarried. Salary £150 per annum, with board and laundry.

EXETER CITY ASYLUM.—Medical Superintendent. Salary £500 per annum, with unfurnished house, coal, lighting, laundry, &c.

GLASGOW UNIVERSITY.—Examiners.

GLOUCESTER, GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £140 per annum, with board, lodging, and washing.

HARROW-ON-THE-HILL URBAN DISTRICT COUNCIL.—Medical Officer of Health. Salary at rate of £200 per annum.

HUDDERSFIELD ROYAL INFIRMARY.—Senior and Junior Assistant House Surgeons. Salary £80 per annum each, with board, rooms, and washing.

HULL ROYAL INFIRMARY.—Senior House Surgeon, unmarried. Salary £150 per annum, with board and apartments. Also Assistant House Surgeon. Salary at rate of £100 per annum, with board and lodging.

IPSWICH, EAST SUFFOLK HOSPITAL.—Resident House Physician

KILMARNOCK INFIRMARY.—Female House Surgeon. Salary £80 per annum, with board, &c.

KING'S LYNN, LYNN AND WEST NORFOLK HOSPITAL.—House Surgeon. Salary £150 per annum.

LEICESTER, LEICESTERSHIRE EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary at rate of £300 per annum.

LIVERPOOL, BROWNLOW HILL INSTITUTION.—Resident Assistant Medical Officer. Salary £140 per annum, with apartments.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon. Salary £50 per annum.

MACCLESFIELD, PARKSIDE ASYLUM.—Medical Superintendent. Salary £650 per annum.

MAIDSTONE, KENT COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £280 per annum, with board, quarters, attendance, washing, &c.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—Resident Medical Officer, unmarried, for six months. Salary at rate of £100 per annum.

MANCHESTER, COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

MANCHESTER, HULME DISPENSARY, Dale-street, Stretford-road.—House Surgeon. Salary £180 per annum, with apartments, attendance, coal, and gas.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

MANCHESTER POOR-LAW INSTITUTION, Crumpsall.—Second Resident Assistant Medical Officer and Junior Resident Assistant Medical Officer, both unmarried. Salary £180 and £160 per annum respectively, with rations, apartments, fire, light, washing, and attendance.

MANCHESTER ROYAL EYE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with residence, board, and washing.

NEWCASTLE, CO. WICKLOW, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION FOR IRELAND.—Assistant Resident Medical Officer. Salary at rate of £200 per annum, with board and residence. Also Laboratory Assistant. Salary £1 per week and cottage.

NEWCASTLE-UPON-TYNE, HOSPITAL FOR SICK CHILDREN.—Senior Medical Officer. Also Junior Medical Officer. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.

NEWCASTLE-UPON-TYNE AND NORTHUMBERLAND SANATORIUM FOR CONSUMPTIVES, Barrasford, North Tyne.—Resident Medical Officer, unmarried. Salary £350 per annum, with board, residence, and laundry.

NEWPORT (MON.), ROYAL GWENT HOSPITAL.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

NORTHAMPTON GENERAL HOSPITAL.—Two House Surgeons. Salary £120 per annum, with apartments, board, washing, attendance, &c.

NOTTINGHAM CHILDREN'S HOSPITAL.—Female House Surgeon for six months. Salary at rate of £130 per annum, with apartments, board, and washing.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £100 per annum, with board, residence, and laundry. Also Senior House Physician. Salary £120 per annum, with board, residence, and laundry.

OLDHAM ROYAL INFIRMARY.—Third House Surgeon for six months. Salary at rate of £100 per annum, with board and residence.

PRESTON, COUNTY ASYLUM, Whittingham.—Junior Assistant Medical Officer, also Assistant Medical Officer to also act as Pathologist, unmarried. Salary commencing £250 per annum, with board, apartments, &c.

PRESTON ROYAL INFIRMARY.—Assistant Resident Medical and Surgical Officer. Salary £120 per annum, with board, residence, and laundry.

PUTNEY HOSPITAL, Putney Common, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry.

RICHMOND, SURREY, ROYAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, apartments, and washing.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Junior Resident Medical Officer. Salary at rate of £70 per annum, with board and washing.

RYDE, ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House Surgeon, unmarried. Salary £115 per annum.

ST. ALBANS, HERTS COUNTY ASYLUM, Hill End.—Second Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, and washing.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—Temporary Pathologist and Bacteriologist. Salary at rate of £100 per annum.

ST. MARYLEBONE INFIRMARY, Packham-street, Notting Hill, W.—First Temporary Assistant Medical Officer, unmarried. Salary £225 per annum with apartments, rations, and washing.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Resident Medical Officer and Assistant Resident Medical Officer. Salary at rate of £110 and £90 per annum respectively, with board, residence, and laundry.

SHIPWAY.—On Oct. 25th, at 61, Queen Anne-street, W., the wife of Francis E. Shipway, M.A., M.D. Cantab., of a daughter.

MARRIAGES.

CAPON—SEELY.—On Oct. 24th, by special licence, at St. John's Church, Paddington, by the Rev. Canon Lillingston, M.A., Herbert Vawdrey Capon, 2nd East Anglian Brigade, R.F.A., only son of Dr. and Mrs. H. J. Capon, of 40, Upper George-street, W., to Ruby, daughter of the late Mr. Alfred Seely and Mrs. Seely, The Gables, Gressenhall, Norfolk.

COCKCROFT—PEACOCK.—On Oct. 28th, at St. Mary's and St. Alkelda's Church, Middleham, by the Rev. H. G. Topham, M.A., George, second son of the late William Cockcroft, Solicitor, Rochdale, and Mrs Cockcroft, Middleham, to Mary, second daughter of M. D. Peacock, Manor House, Middleham. At Home, Dec. 2nd and 3rd.

COLLINS—MERRICK.—On Oct. 21st, at St. Mary's, Barnes, Algernon Boniface Collins, M.R.C.S., L.R.C.P., to Marie Adéle, eldest daughter of Mr. and Mrs. William Gordon Merrick, of Barnes, S.W

DEATHS.

SHINE.—On Oct. 22nd, at Galtee More, Barnsley, John Power Shine, M.B., Ch.B. R.U.I., aged 45.

SIMPSON.—On Oct. 22nd, at Horton-crescent, Rugby, James Herbert Simpson, M.D., aged 64.

SMITH.—On Oct. 23rd, Eliza Jane, the loved wife of John Percival Smith, L.R.C.P., at 370, London-road, South Lowestoft.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

HEALTH AND SANITATION IN THE BAHAMAS.

ACCORDING to the Blue-book of the Bahamas, just received at the Colonial Office, the estimated population of the islands on Jan. 1st, 1914, was 55,766. The births in 1913 numbered 1907, as against 1824 in 1912. The deaths were 1433, as against 1498 in 1912. The birth-rate was 34 per 1000, and the death-rate 25·6 per 1000. Whooping-cough was epidemic during the year over the whole colony. There were 30 cases of typhoid fever, of which 8 died. The mean temperature for the year was 78·1, and the rainfall 39·96 inches. As regards water-supply, the commonest source is wells. From an analysis which has been made at the Imperial Institute it appears that the water is hard, contains large proportions of chlorine, and is in most instances polluted. The other source of supply is rain water stored in tanks, tubs, and underground cisterns. The services of a noted expert, Mr. H. H. Humphreys, were obtained with the view of demonstrating whether a supply of fresh water sufficient for the needs of the city and suburbs of Nassau could be obtained by boring or otherwise, and his report is to be laid before the House of Assembly.

The Bahamas General Hospital was established in 1809 as a poorhouse and hospital for the poor and infirm of the island. Since then the institution has grown steadily, and its functions have been extended in many directions. In 1845 it was placed under a Board of Commissioners appointed by the Governor, and now comprises the hospital proper, the infirmary, dispensary, the lunatic asylum, and the leper compound. The feasibility of forming a leper colony on one of the small islands is under consideration. This is necessary if the Lepers Act, 1913, which provides for compulsory segregation in certain cases, is to be made operable. As a winter health and pleasure resort Nassau (the capital) has for many years past attracted a considerable number of American and Canadian visitors. It is estimated that during the year about 2600 tourists arrived, in addition to 1231 visitors from pleasure steamers staying a few hours on their way north or south.

A MEDICAL FAMILY.

To the Editor of THE LANCET.

SIR,—The death of Mr. Alfred Pern, F.R.C.S., on Oct. 12th, at Botley, Hants, briefly noted in THE LANCET of Oct. 17th, p. 975, recalls a noteworthy fact. He was the father of a large family, among whom were no fewer than seven sons, all educated at Marlborough College and possessing the same medical qualifications (Conjoint M.R.C.S., L.R.C.P.) all being at present in practice, four in England and three in Australia. I venture to think this must be a record.

I am, Sir, yours faithfully,
London, Oct. 28th, 1914. SEPTEM.

CENTIGRADE AND FAHRENHEIT.

To the Editor of THE LANCET.

SIR,—As I observe that your readers are interested in methods of converting degrees Centigrade into degrees Fahrenheit, you might like to publish the following original mechanical method of making rough thermometer scales. Take a piece of plain paper, not too thick, and measure off a length of seven inches. Fold it four times in half successively and neatly. The paper will have 15 creases. Starting from the bottom crease number the first crease 8, the next 16, the next 24, the next 32, and so on, up to 120 at the top crease. This paper will now act as a Fahrenheit scale, the 32 crease being the freezing point, at which lay the end of a foot-rule or inch measure, and mark on the paper 0 Centigrade opposite the 32 Fahrenheit; then one inch up the rule mark 10° C., at two inches up mark 20° C., and so on. Of course each half inch up will be 5° C. extra, and thus two and a half inches will be 25° C., and if the rule should be divided into tenths of an inch all the degrees can be marked off on the paper easily. As regards the Fahrenheit scale, it is obvious that each crease marking off 8° it can easily be further halved into 4°, and again into 2°, and thus completed in detail if required. For a rough and ready method it will be found very close to accuracy. All that is required is a piece of paper and an inch measure.

I am, Sir, yours faithfully,
London, Oct. 23rd, 1914. F.

THE Buxton council have resolved "that all officers, soldiers, and sailors of the Allied Forces invalided to Buxton be granted the Buxton mineral water treatment free of cost, such treatment to be prescribed by a medical practitioner." It is hoped that this offer will be extensively taken advantage of, as the waters of Buxton, combined with the dry bracing air, should be of particular value in cases of rheumatism contracted by our army and allies whilst in the trenches.

Dr. D. Barty King will give a lecture, illustrated by the epidiascope, on "Germany in War Time," with an account of his experiences amongst the German wounded, to the nurses of the Tuberculosis School of the Royal Hospital for Diseases of the Chest, City-road, on Nov. 3rd.

THE Thermogene Company, Limited, desire to make it known that Thermogene was invented by a Belgian chemist, Charles Vandenbroeck, of Brussels, from whom it was acquired by the present British proprietors. It is entirely British owned and made by British labour at the company's factories at Haywards Heath, Sussex.

WE are asked to state that the War Office has accepted a gift of 500 gallons of Acrosyl to be distributed amongst the military hospitals in the United Kingdom. Acrosyl is a saponified cresylic disinfectant containing 50 per cent. of specially treated cresols.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Hon. R. J. Strutt: Luminous Vapours Distilled from the Air, with Applications to the Study of Spectrum Series and their Origin. II.—Prof. J. N. Collie, Mr. H. S. Patterson, and Mr. I. Masson: The Production of Neon and Helium by the Electrical Discharge.—Prof. C. H. Lees: On the Flow of Viscous Fluids through Smooth Circular Pipes.—Mr. F. O. Rice: Quantitative Measurements of the Absorption of Light. I., The Molecular Extinctions of the Saturated Aliphatic Ketones (communicated by Prof. E. C. C. Baly).—Prof. W. M. Thornton: The Ignition of Gases by Condenser Discharge Sparks (communicated by Sir Charles Parsons).—Mr. E. G. Bilham: The Spark Spectrum of Nickel under Moderate Pressures (communicated by Mr. A. Fowler).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY.

SECTION OF OPHTHALMOLOGY (Hon. Secretaries—Leslie Paton, Elmore W. Brewerton): at 8 P.M.

Cases:

Mr. A. Hugh Thompson: (1) Complete Loss of Pupillary Light Reflex in One Eye with Retention of Contraction to Convergence; (2) Persistent One-sided Loss of Pupillary Reflex in a Healthy Adult.

Mr. Bishop Harman: (1) Congenital Entropion; (2) Notes of a Case of High Myopia in an Infant.

Papers:

Mr. Holmes Spicer: Bubbles in the Anterior Chamber.

Mr. H. B. Grimsdale: The Necessity of a Definition of Blindness.

FRIDAY.

SECTION OF LARYNGOLOGY (Hon. Secretaries—Cecil I. Graham, W. D. Harmer): at 4 P.M.

Cases and Specimens:

Will be exhibited by Dr. Hill, Dr. Lambert Lack, Dr. Dan McKenzie, Mr. Herbert Tilley, Dr. Coubro Potter, Dr. Irwin Moore, Dr. Jobson Horne, &c.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Meeting.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, Society's Rooms, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., Special Clinical Evening.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Bradshaw Lecture:—Dr. N. Tirard: Some Clinical Contributions to the Study of Glycosuria.

THURSDAY.—5 P.M., Dr. C. A. Mercier: Leper Houses and Mediæval Hospitals.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Museum Demonstrations for Advanced Students and Medical Practitioners:—

MONDAY.—5 P.M., Mr. S. G. Shattock: Specimens illustrating Repair.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynæcological (Dr. J. B. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Nose, Throat, and Ear (Mr. H. D. Gillies). X Rays and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 4.30 P.M., Special Demonstration of Selected Skin Cases. 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:- Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

CHARING CROSS HOSPITAL, Chandos-street, Charing Cross, W.C.

MONDAY.—3 P.M., Huxley Memorial Lecture on Recent Advances in Science in Relation to Medicine and Surgery:—Sir Ronald Ross: Malaria and the Transmission of Diseases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Lecture:—Mr. L Paton: Clinical Cases.
FRIDAY.—3.30 P.M., Lecture:—Mr. L. Paton: Clinical Cases.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Sebaceous Dermatitis.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill street.—4.30 P.M., Dr. A. Renshaw: Collection of Pathological Material for Examination.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Abnormal Presentations (continued). 11 A.M., Examination of Patients and Minor Operations.

TUESDAY.—10 A.M., Major Operations.

WEDNESDAY.—10 A.M., Obstetrical Lecture: Asphyxia Neonatorum. 11 A.M., Examination of Patients and Minor Operations.

THURSDAY.—10 A.M., Major Operations.

FRIDAY.—10 A.M., Gynæcological Lecture: Genital Prolapse. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Shapley, Cambridge; Salford Royal Hospital, Secretary of; Sheffield Children's Hospital, Secretary of; St. Mary's Hospital for Women and Children, Plaistow, Secretary of; *Staffordshire Sentinel* Advertising Bureau, Hanley.

T.—Tuberculosis League, Pittsburgh, Secretary of; Dr. Leonard H. Taylor, Kota Bharu, Kelantan.

U.—University of Glasgow, Registrar of; University of London, Principal of.

V.—Dr. H. J. Van Praagh, Lond.

W.—Messrs. Winter, Birmingham; Mr. G. E. Walker, Camblesforth; Dr. A. G. Wilkins, Manchester; Messrs. J. Wright and Sons, Bristol; Mr. A. Wilson, Lond.; Messrs. J. Woodhead and Sons, Huddersfield; Messrs. E. Westmacott and Co., Lond.; Warrington Infirmary, Secretary of; Dr. S. A. K. Wilson, Lond.; Mr. Walter Watson, Hull; Wellcome Historical Medical Museum, Lond., Curator of; Dr. F. J. Wethered, Lond.; West London Hospital Post-Graduate College, Dean of; West Kent General Hospital, Maidstone, Secretary of; Walsall and District Hospital, Walsall, Secretary of; Messrs. Williams and Son, Bradford.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. H. G. Adamson, Lond.; Mr. E. G. B. Adams, Newbery; Anglo-Newfoundland Development Co., Lond.; Ayr District Asylum, Clerk to the; Messrs. C. Ash, Sons, and Co., Lond.; Mr. E. Arnold, Lond.

B.—Mr. C. A. Ballance, Lond.; Dr. W. H. H. Bennett, Batley; Dr. D. Brown, Greenock; Bristol General Hospital, Secretary of; Bishopstone House, Bedford, Medical Superintendent of; Bristol Royal Hospital for Sick Children, Secretary of; Bristol City Asylum, Clerk to the; Barnwood House Hospital, Gloucester, Medical Superintendent of.

C.—Mr. T. A. B. Cooke, Milford; Messrs. Cox and Co., Brighton; Dr. Angus Cameron, West Hartlepool; County Asylum, Prestwich, Clerk to the; Coventry, &c., Hospital, Secretary of; Central London Throat and Ear Hospital, Secretary of; Messrs. E. Cook and Co., Lond.

D.—Mr. W. P. Dester, Turriff; Davis Gas Stove Co., Lond.; Devonport Guardians, Clerk to the; Dumfries and Galloway Royal Infirmary, Secretary of; Mr. J. H. Dauber, Lond.; Dr. H. Dutch, Lond.; Messrs. Duncan, Flockhart and Co., Edinburgh.

E.—Messrs. Everett and Son, Lond.; Messrs. A. R. Elliott, New York.

F.—Dr. Y. Farag, Cairo; Farringdon General Dispensary, Lond., Secretary of; Fellows Medical Manufacturing Co., New York; Messrs. Fry and Sons, Bristol.

G.—Dr. H. Gilliland, Lond.; Dr. J. G. Gordon-Munn, Ipswich; Messrs. Gale and Co., Lond.; Grove House, Church Stretton, Medical Superintendent of; Dr. J W. Grange, Manchester.

H.—Mr. W. Heinemann, Lond.; Mr. J. Heywood, Manchester; Home for Epileptics, Maghull, Secretary of; H. L., Hampstead; Hornsey Borough, Lond., Accountant to the; Haydock Lodge Retreat, Newton-le-Willows, Secretary of; Miss Hastie, Lond.; Mr. W. H. Heygate, Belvedere; Dr. B. Hall, West Mersea; Messrs. J. Haddon and Co., Lond.; Messrs. T. Holland and Son, Lond.; Messrs. Hogg and Son, Lond.

J.—Mr. H. A. Jeffery, Bradford; Dr. F. Silva Jones, Lond.; Jeyes' Sanitary Compounds Co., Lond.; Mr. J. R. Jones, Neath; J. K.

K.—King Edward VII. Hospital, Cardiff, Secretary of.

L.—Mr. T. S. Logan, ond.; Mr. R. L. Legate, Christchurch; Luton Corporation, Accountant to the; Leicester Royal Infirmary, Secretary of.

M.—Mr. S. Moberly, Winslow; Dr. J. W. McLeod, Aldershot; Mr. R. Mackay, Bettyhill; Dr. D. I. McLeish, Cockermouth; Manchester Corporation, Treasurer of; Colonel Magill, Lond.; Manchester Royal Infirmary, Secretary of; Manchester Hospital for Consumption, Secretary of; Dr. T. D. Moffat, Ardgay.

N.—Nottingham General Hospital, Secretary of; Nottingham General Dispensary, Secretary of; Dr. D. Newman, Glasgow.

O.—Messrs. Osborne and Co., Lond.

P.—Dr. John Pender, Barnsley; Dr. E. F. Pratt, Newcastle-on-Tyne; Miss Pring, Bristol; Price's Patent Candle Co., Lond.; Portsmouth Lunatic Asylum, Clerk to the; Mr. C. F. Price, Minchinhampton; Mr. R. J. Pye-Smith, Sheffield; Prudential Assurance Company of America, Newark, Secretary of.

R.—Messrs. Roberts and Co., Lond.; Royal Samaritan Hospital for Women, Glasgow, Secretary of; Dr. A. Routh, Lond.

S.—Dr. H. J. Simson, Edinburgh; Mr. J. P. Smith, Lowestoft; Mrs. Somerville, Dalkeith; Dr. Purvis Stewart, Lond.; Scarborough Hospital, &c., Secretary of; Somerset County Council, Weston-super-Mare, Clerk to the.

T.—Dr. J. P. Tildesley, Willenhall; Taunton and Somerset Hospital, Taunton, Secretary of; Messrs. Thacker and Co., Lond.; Miss Thompson, Winnipeg; Mr. W. H. Thomas, Bath.

V.—Mr. J. W. Vickers, Lond; Victoria Children's Hospital, Hull, Secretary of.

W.—Mr. J. E. Wright, Lond.; Warneford Asylum, Oxford, Medical Superintendent of; Mr. C. J. Witts, Lond.; Messrs. W. Wood and Co., New York; Dr. W. Watkins-Pitchford, Lond.; Dr. A. B. Wade, Ryde; Whitehaven Infirmary, Secretary of; Woodhall Spa Co., Woodhall Spa, Secretary of; Mr. T. F. Wyse, Gorey; West Riding County Council, Wakefield, Accountant to the; Worcester County and City Asylum, Clerk to the; Miss Wrightson, Littlehampton; Messrs. W. J. Wilcox and Co., Lond.

The Huxley Lecture

ON

RECENT ADVANCES IN SCIENCE AND THEIR BEARING ON MEDICINE AND SURGERY.

MALARIA AND THE TRANSMISSION OF DISEASES.

Delivered at Charing Cross Hospital on Nov. 2nd, 1914,

BY SIR RONALD ROSS, K.C.B., F.R.S., M.D., F.R.C.S., D.Sc., LL.D., D.P.H.

MR. CHAIRMAN, LADIES, AND GENTLEMEN,—I can imagine nothing that would have delighted Huxley more than the bearing of recent advances in science on the medicine of the tropics. Indeed, this latest victory of science, achieved after his time, may be considered as a culminating point in the practical application of science to the needs of suffering humanity. The victory has been won, not only by medicine, but by medicine and zoology fighting side by side—by those two great branches of science in which he himself was so proficient. Let me now describe the details of the campaign.

THE TRANSMISSION OF DISEASE.

It is curious that though the transmission of disease is a matter of such vast import to every one of us, it has received so little investigation in the past. Even up to the middle of last century our inquiries had led us little further than what I call the subscience of the subject—that is, we distinguished, classified, and named our various bodily inflictions. We also did more: for we had ascertained empirically the physiological and therapeutical effect of many drugs—quinine, opium, mercury, iodide of potassium, ipecacuanha, and others; and also that great genius Jenner had discovered a wonderful fact which is at the basis of the theory of immunity, prevention, and cure. But the causes of disease and their mode of transference still remained hidden. At that epoch, however, and afterwards Pasteur, Koch, Lister, Behring and others created the science of bacteriology. But still, though the information thus obtained was of prime importance to the pathologist, the physician, and the surgeon, we still remained much in the dark regarding one important issue, namely the exact path of transmission of many diseases from man to man. Bacteria are easily saprophytic and may have many paths of transmission, and I fear that we are still very much in doubt as to the most important of these numerous routes. We thought, and are often still inclined to think, that the germs of disease come to us from any place where they may be scattered—that they have not precise routes and points of entry. This leads to a very vague prophylaxis. We undertake all kinds of disinfections in order to destroy the enemy wherever he may possibly lurk; and the consequence is that we often fail to check infection as certainly as we wish. It has been the great result of the inquiries which I will now proceed to describe that they have, as the French say, "precised" our knowledge upon this point in connexion with many diseases, and have indeed led to the discovery of another and most wonderful route of infection which until recently was undreamed of by the profession and the public.

The armies of science, like those of nations, commence with small beginnings and advance in parallel columns. If one column is checked by insuperable difficulties, the others endeavour to outflank the point of resistance; and a victory is often won by this means in science as in war. (Excuse my military similes, which appear to be appropriate at this hour.) That column of science which conquered the domain of bacteriology was brought to a standstill for some time as regards the exact transmission of disease until the parallel column attacking from quite a different direction circumvented the difficulty in this respect.

The Story of the Early Investigations.

The story commences with the studies of those obscure and often despised workers who toiled in the domains of parasitology. Some of the largest parasites were known in antiquity, but the ancients possessed quite a wrong notion of their origin, which they attributed to spontaneous generation—that is, they thought the parasites originate *de novo* in the host. In the seventeenth century, however, Redi proved that this hypothesis does not hold for certain insects; and later Pallas argued that parasites originate *ab ovo*, like other animals—that is, that their eggs escape from one host and enter another host, thus leading directly to the presence of the parasites in the latter. This history possibly still holds for certain parasites; but in 1790 Abildgaard showed by experiments that some parasites of fish live not only in those fish but for a part of their existence in certain water fowl; and this extraordinary law, which may be called after De Barry's term slightly changed, the law of metaxeny, was proved during the middle of last century by Eschricht, Steenstrup and especially Küchenmeister to apply to a large number of Platodes and Cestodes. Subsequently Leuckart, Melnikoff, and others extended the law to cover other species, including species of Nematodes. A most important case was that of the *Filaria medinensis*, the famous guinea worm of man, which was shown by Fedschenko in 1869, following a suggestion of Leuckart, to be in common with man and a water-flea (*Cyclops*). All this constituted a discovery which was both remarkable in that it exhibited the wonderful devices of nature for propagating parasites from host to host, and was also of the highest importance to mankind (though few recognised this point at the time) because it showed us how many of our great diseases are likely to be acquired.

Let me dwell on this point for a moment. Parasites, accustomed as they are to dwell in the safe retreats of certain portions of their host's body, must be exposed to great dangers whenever they come to pass, as they must do, from one individual host to another. Thus if this passage is effected merely by the egg, it is obvious that the eggs must be poured out in immense numbers to compensate for their immense destruction outside the body of the host, while it would always be probable that only a very minute proportion of the eggs would ever find their way again into fresh hosts of the proper species. In order to avoid these difficulties, nature, I presume through an infinite period of evolution, has enabled many parasites to acquire a more safe and certain route of entry—through other animals which are associated frequently with their first species of host. Thus, for instance, a parasite of dogs and cats develops also in the dog-louse, and is therefore not scattered broadcast from the dog and the cat over the surface of the earth, but is retained alive in close proximity to the bodies of those animals. Remember that nature is as solicitous for parasites as for the higher animals which contain them. She thinks no more of man than of the minute germ which infests him. From her open hand fall innumerable species, and she endows them all with equal powers of looking after themselves and their own interests. It is not in the interest of parasites to be wasted abroad. It is in their interest to be brought again as quickly as possible to the host in which evolution has formed them to live—and that is why this wonderful law of metaxeny holds good. It must be remembered, of course, that no species of parasite should be allowed to develop in excessive numbers in the same individual host, because this would result in the death of the latter and therefore also of the former. The parasite must therefore find some means of transference at some stage in its life-history; and that route must be the most expeditious possible. This most expeditious route will often be, as I have said, through another species of animal connected in its habits with the original host.

Later Discoveries.

Following upon the discovery of Fedschenko, Manson in 1877 showed that the embryos of another *Filaria* of man (*Filaria bancrofti*) develop in a species of mosquito, probably a *Culex.* The life-cycle of this parasite, up to the point to which he carried it, was closely similar to that demonstrated by Fedschenko for *Filaria medinensis*; and Manson did not complete the story. Now, however, other important discoveries were made, which showed that animal parasites do not by any means belong only to the zoological groups of the Cestodes, Platodes, and Nematodes, but that many of them are unicellular. Thus Leuckart established the protozoal order of the Sporozoa; Lankester and others discovered Trypanosomes and Hæmogregarines; Davaine discovered Cercomonads, and Lösch discovered the group of parasitic amœbæ. Lastly, in 1880, Laveran made the most important discovery that malaria is associated with a minute protozoal parasite of the blood; and his observations were followed by those of Danilewski and others who showed that similar parasites are to be found in many animals. All this extended the catalogue of animal parasites over a vastly larger field than was known to the ancients; and the morphology and life-history of the parasites in the known hosts were elaborated by numbers of workers, who also succeeded gradually in connecting them with some of the most important diseases which inflict man and animals. Thus it was gradually shown that amœbæ are the cause of one form of dysentery and abscess of the liver; that trypanosomes cause the deadly nagana of domestic animals in Africa, and the equally deadly sleeping sickness of man, besides many other maladies of animals of numbers of species. Ankylostomes were proved to cause miner's anæmia, which also was shown to be prevalent through vast areas of the tropics, by no means only among miners. The Trematodes called *Bilharzia* were shown to produce a terrible form of cystitis in Egypt and elsewhere. *Filaria bancrofti* were proved to produce elephantiasis and a number of other maladies which are very common in the tropics. Simultaneously malaria was seen to be caused by at least three different species of the group discovered by Laveran.

At the same time, of course, as I have said, the habits of all these parasites in the hosts in which they had been found were being minutely examined. But up to the last decade of last century we still could form scarcely any definite idea as to how the protozoal parasites pass from one individual host to another. The law of metaxeny which had been proved to apply to many of the larger parasites had not been extended to the smaller ones. In 1889, however, Smith and Kilborne discovered a small parasite called *Piroplasma*, in the blood of cattle suffering from Texas fever; and more than that showed that in some mysterious way the infection is carried from ox to ox by means of certain cattle-ticks—though they did not demonstrate in any way that these parasites undergo a metaxenous stage of development in the ticks, and indeed failed to find them at all in these arthropods. In 1896 also Bruce made his famous discovery that the Trypanosomes of nagana are conveyed by certain tsetse flies, but supposed that the carriage is a mechanical one. And there the matter rested until the solution of the great malaria problem opened a new field.

MALARIA.

We now turn to the subject of malaria. Economically, as well as medically, it is certainly the most important disease in the tropics, perhaps in the world. It is found almost everywhere in hot climates, and even in most temperate climates during the summer. From statistics we find that as a broad general rule in malarious countries about one-third of the total population suffer from attacks every year, and also that about one-third of the admissions to hospital and attendances at dispensaries are due to malaria. But these figures are merely based upon records and do not cover the enormous additional number of patients who remain untreated. Thus we know that the malaria parasites or malarial enlargement of the spleen can be found in native children in malarious countries to an enormous extent, reaching 100 per cent. in very insalubrious spots. The case mortality is only about 0·5 per cent., but the prevalence of the disease is so extremely great that the total mortality caused by it makes an addition to the general mortality of anything up to 10 per 1000 or even 15 per 1000; and the malady complicates all other diseases in the tropics in a way which renders them more difficult to treat. In India alone it has been officially estimated that the total deaths from malaria average about 1,300,000 a year in ordinary years, and may reach a much higher figure during years of epidemic prevalence. Thus the total bill of annual mortality and sickness which King Malaria presents to the human race is something enormous.

Former Hypotheses regarding Malaria.

Hence the development of the human race, especially in warm countries, has long demanded that we should ascertain exactly how this plague is propagated, and should endeavour to find how best it may be prevented. It is remarkable that even more than 500 years before Christ the ancients certainly were acquainted with one great law—namely, that malaria is connected with stagnant water, such as marshes; and there are good grounds for believing that Empedocles of Sicily actually delivered Selinus from malaria by draining its marshes or by turning two rivers into them. This knowledge seems to have been generally held since ancient times, though it must have been acquired quite empirically; but Varro and Columella, at about the time of the Christian era, actually suggested that the disease is in some way connected with insects which breed in marshes. In more modern times, however, malaria has been ascribed to noxious vapours given off by stagnant collections of water—the hypothesis evidently being that the poison is some kind of chemical one. I have mentioned that in 1880 Laveran discovered that the disease is due to certain protozoal parasites in the blood. When this fact was accepted ten years later, many observers at once rushed to the conclusion that these parasites have an extra-corporeal existence in marsh water, and actually attempted to demonstrate this by producing infection in healthy persons by such water brought from malarious localities. The experiments of Agenore Zeri (1890) are to be particularly mentioned. He gave water from the Pontine marshes persistently to a number of persons orally or in spray or by clyster, but entirely without result. At the same time many thought that the poison may lie, not only in stagnant water, but generally in the soil of warm countries, this being called the hypothesis of the telluric miasma; but of course this was merely a hypothesis which did not rest upon any observations or experiments. Even ten years after Laveran's discovery we were still completely ignorant as to how the malaria parasites enter the body. We might search for them in marshes and soil; but the search was likely to prove extremely difficult, because all water and soil is full of innumerable different organisms, and it would have been no light task to ascertain which of all these are really responsible for the disease among men, especially since Zeri had shown how difficult it was to produce infection by means of water in bulk.

At the same time however, the hypothesis originally but vaguely mooted by Varro and Columella had been gaining ground. Indeed, Lancisi had repeated the same speculation in 1717 and seems actually to have suspected mosquitoes and to have studied them. As late as 1881 several theorists repeated this conception—though, on studying their statements, I think that little value is to be attached to them. In 1883, however, Dr. A. F. A. King wrote a most able paper on the subject, in which he gives no less than 19 reasons why mosquitoes are likely to carry malaria. He thought that the insects bring the poison from the marsh and inoculate it into men. Many of his reasons are good ones, but others are now seen to have been untenable—and, in any case, he gave no experimental evidence. Next year Laveran himself and Robert Koch independently enunciated the same speculation, but gave few reasons and no experiments in support of it. Ten years later, however, Manson repeated the hypothesis, but in a different form. He depended less upon the epidemiological evidence cited by King than upon certain parasitological evidence which occurred to himself. By this time (1894) the parasites of malaria had been very carefully studied, and were shown to possess, not only certain forms which are provided for their propagation in the human host, but also other forms which, when the blood is freshly drawn, emit several so-called flagella. These latter forms had really led Laveran to his discovery, but their zoological significance still remained quite unexplained; and while some writers thought that they had some special significance, others believed them to be merely the result of death *in vitro*. Manson now urged that the flagella given off from these forms are really flagellated spores; that when mosquitoes ingest blood containing these forms the flagellated spores escape in the insect and enter its tissues, where they ripen into some further unknown stage. Then, he thought, the insect dies two or three days later on the surface of the water, and this later stage of the parasites enters the water, and finally rises in the marsh-mist to infect men. Obviously, therefore, Manson's hypothesis was quite different from King's: the former thought that mosquitoes derived the parasite from men and transferred it to the marsh, while King thought just the opposite. Neither really reached the truth: both were half right, but half wrong. One cited parasitological and the other epidemiological evidence; and neither attempted experimental verifications.

The Solution of the Problem.

Nevertheless, all these hypotheses, including those of the telluric miasma, were necessary for the laborious experimental inquiry which was now evidently demanded in the supreme interests of human life and health. I gather from what I have been told that my own work on the subject may prove sufficiently interesting to students to be worthy of mention here. I was first drawn to the malaria problem in the year 1889, when I observed during active service in Burma that the prevalence of malaria did not at all accord with the theory of the telluric and marsh miasma; and my doubts were strengthened during subsequent years by careful thought and study. If the poison is given off in an aerial form, either from water or from soil, the disease ought to be almost uniformly distributed. Such, however, is not the case, and it really occurs principally in very small spots or pockets, generally in close proximity to stagnant water. Thus in one station where I subsequently served my regiment was severely inflicted, while other regiments, scarcely a mile distant, remained almost entirely free. I was therefore very dissatisfied with this hypothesis, and being acutely alive to the great importance of the problem I determined to study it carefully. In 1894 Manson acquainted me with his hypothesis, and I then remembered that Laveran had said the same thing; but I was not aware of King's paper, nor of the remarkable researches on *Piroplasma* by Smith and Kilborne. In 1895 I attacked the work experimentally at Secunderabad in India, and determined first to adopt the mosquito speculation as a working hypothesis, and then to study other hypotheses if it failed—though I was much impressed by the former. The whole history of my work has been fully given in my Nobel Lecture, published in England by the Journal of the Royal Army Medical Corps, 1905; and I need mention here only the salient points.

For more than two years I caused mosquitoes of the genera *Culex* and *Stegomyia* to feed on patients containing malaria "crescents" which were the proper forms for transmission according to Manson. But my failure was complete, and indeed it was impossible to follow what he thought were flagellated spores in the insects' tissues. I then adopted another technique; which was to compare insects of the same species which had been fed on malarial blood with those which had not been so fed, and to see if I could find any particular parasites in the former after they had been kept alive for some days. Many hundreds of insects were studied completely in this manner, and more than a thousand incompletely; but my failure was still complete. I obtained, however, a close practical experience of the insects' tissues, and learnt much about some common parasites which they possess. I also endeavoured to infect healthy persons by means of water in which presumably infected mosquitoes had been allowed to die, as Manson thought that such water would be infected; and, lastly, I worked at a hypothesis of mine, that infected mosquitoes might carry infection by their bites, and Mr. Appia, assistant surgeon of my hospital at Bangalore, kindly submitted to be bitten by many such insects in 1896. The result still remained quite negative. We now know the reason: the species of insect with which I was working were the wrong ones.

In 1907, however, I observed another variety, which I called dappled winged mosquitoes, and which everyone now knows were Anophelines. I first saw these in an intensely malarious quarter near Ootacamund, where I myself acquired malaria during my investigations. A few months later I obtained eight of these insects in Secunderabad, and employed them for my usual experiments. Six of them died or gave bad dissections. On August 20th, 1897, I was so fortunate as to find in the tissues of one of these insects, four days after it had been fed upon a case of malaria, certain bodies which I had never observed in mosquitoes before. These contained the characteristic pigment of the malaria parasite. Next day, the 21st, I found the same bodies in the last mosquito of my batch of eight—only they were now larger and more definite. To those who had not worked at the subject such evidence might appear slight indeed; to me, after years of toil and thought, the evidence was immensely strong. A little later I found the same bodies in two more mosquitoes and knew that I was on the right track: I felt that the two unknown quantities of this complex equation had been simultaneously found—the species of mosquito which carries malaria, and the position which the parasites take in its tissues, namely, the wall of the intestine.

Elucidation of Life-Cycle of Malaria Parasites.

Now, after 17 years, I may perhaps be allowed to mention this point in order to encourage those students who, as I was then, are now toiling after the unknown. But I at least obtained success, not only by labour but also by supreme good fortune; and believe that but for this good fortune on those dates, we should still have remained ignorant of the manner in which malaria is conveyed, and might have remained ignorant of it for the next century. Unfortunately, my work was now interrupted for nearly six months, just at a point when I expected to unravel the whole history of the malaria parasites in a few weeks; and it was not until March of next year that I was able to take up the thread again in Calcutta. For many reasons I was then unable to work at the human parasites, but commenced the study of the malaria parasites of birds, which are closely similar to the former. In a very short time I was able to demonstrate the presence in mosquitoes of pigmented bodies derived from the allied parasites. These bodies were found to grow regularly during one week after the insects had been fed; to reach maturity, and to produce a number of elongated spores. Now came an intensely exciting moment. What happens to these spores? According to Manson's hypothesis, they ought to liberate themselves in the water in which the insects died; but I had now shown that the insects did not die after two or three days as he supposed, but may live for weeks. I attempted to follow the spores in all directions through the insects' tissues, into the lower intestine, and even into the egg. On July 4th, 1898, however, I observed the fact that the spores enter the insects' salivary or poison glands. The full truth was now immediately disclosed, and proved to be far more wonderful than any of us had ever dreamed of. The parasites are not only taken from man by the mosquitoes as Manson had supposed and are not only put into man by the mosquitoes as King had supposed; but both hypotheses are true, and the insect carries the parasites directly from man to man. Here then was merely another case of the great law of metaxeny—which, however, was now proved for the first time to hold good for protozoal parasites. The malaria parasites, like many larger ones, require two hosts for their life-cycle.

These researches mapped out step by step every detail of the transformation, and gave us a much greater logical certainty than could be obtained by isolated infection experiments. Nevertheless, such experiments were attempted immediately, and in July and August I infected 22 out of 28 healthy birds by the means of the bites of infected *Culex*—thus completing the whole story in detail. True, that was done with birds' malaria, and I had only seen the first steps of the process with regard to human malaria; but any zoologist will know that with such closely allied species the life-cycle of one is sure to be almost exactly similar to the life-cycle of the other—as proved to be the case here. My work was now interrupted again, and for nearly a whole year; and it was not until August, 1899, that I was able to show directly that the human parasites have exactly the same development. Meantime, however, Koch and Daniels had confirmed my work on birds' malaria; and certain Italian workers repeated it with regard to the human parasites, even to causing infection in healthy human beings (November, 1898), three months after my similar work with birds.

A very important discovery had been meantime made quite independently by MacCallum and Opie in America (1897) who showed that the bodies which Manson had thought were flagellated spores were really sperms. Thus the large pigmented cells which I had found in mosquitoes at the same date were really fertilised macrogametes. This gave a much more correct zoological interpretation to my phenomena; but did not otherwise disturb the history which I had ascertained.

SUMMARY OF RESULTS IN REGARD TO MALARIA.

This, then, was the result obtained. Let me summarise it briefly. From the time of the Romans we were aware that the malarial fevers are connected with marshes and stagnant water in warm countries. Later, when it was seen that the disease is not confined only to the proximity of marshes, the theorists conceived that there is a telluric poison which causes malaria and is especially abundant in damp places. All this was a very general proposition; and in order to prevent the disease, it was necessary to undertake very extensive drainage. Now, however, the new knowledge obtained enables us to particularise the exact route of infection. We believe no longer that the poison is spread uniformly in the air of warm countries, but know that it is always contained in the minute bodies of certain insects, and, more than that, in the still more minute salivary glands of those creatures. Here, then, science has given us knowledge which can not fail to be of immense practical importance to the world.

The discovery of the full life-cycle of the parasites enables us, not only to "precise" the route of infection, but to determine exactly which species of mosquitoes are concerned. My failures with numerous undetermined species of the genera *Culex* and *Stegomyia* had shown that these are probably innocuous as regards malaria; and my ultimate success with certain Anophelines had shown that these were inculpated. Since then the work of many observers has shown that out of about 500 Culicidæ only about 25 species carry malaria, and that all of these belong to the Anophelines. So that for the prevention of malaria we are not obliged to deal with mosquitoes in general, but only with particular species.

Still further, the knowledge so obtained enables us to study exactly the habits of the culpable species. In fact, I necessarily began such studies during the whole of my researches. The genera *Culex* and *Stegomyia* breed most commonly in artificial collections of water round houses; but I saw as early as 1897 that the dappled-winged mosquitoes (Anophelines) breed principally in different sites, that is, chiefly in natural collections of water, such as marshes, puddles, streamlets, and the edges of lakes, ponds, and rivers. This had been known before in the case of certain species; but I now saw the great epidemiological and sanitary bearing of the phenomenon. The reason why malaria is connected with marshes was now fully established by quite independent work. Humanity had explained the fact by supposing that the poison of malaria itself rises from the marsh; it was now seen that it is not the poison itself that rises from the marsh but the carrier of the poison. The net result was the same—except that we now know not only the source of the poison but the exact method of transference. After all, humanity had reached the truth by empirical observations made during thousands of years; but now science, in confirming these observations, brought them to a fine point of exact theory.

ADVANCES IN OTHER DIRECTIONS.

But these were by no means the only fruits obtained. To return to our military parallel, when a commanding position of the enemy is carried victory extends to a large area round it. The principal function of men of science is not merely to observe, describe, and catalogue phenomena, but, above all, to solve difficult problems; and the solution of one such problem frequently gives us the solution of many more. Such has proved to be true also in this case; for as soon as we had solved the malaria problem we were able to apply the same theorem to a number of other diseases. As already stated, Manson had shown in 1877 that the embryos of *Filaria bancrofti* can live in certain species of *Culex*, but he had not shown how they pass back from these insects to man. Now, however, James and Low, working independently, showed that the embryos enter the insects' proboscis, thus suggesting that they return into the human circulation by a route similar to that which is used by the parasites of malaria—and this work has been well followed up by Bahr and many others.

Another discovery, concerned with one of the most important of human diseases—namely, yellow fever, was made by Reed, Carroll, Lazear, and Agramonte during the last days of last century. Without knowing the causative agent of that disease, they yet showed by direct experiments on human beings that the infection is carried directly from man to man by another species of mosquito, *Stegomyia fasciata* or *calopus*. It had long been stated by epidemiologists that malaria differs from yellow fever in that the former is connected with damp and decaying vegetation and the latter with insanitary conditions round houses. The former hypothesis was verified by the observation that Anophelines breed in terrestrial waters, and the latter was now explained by the fact that Stegomyia breed in artificial collections of water round houses. A little later Graham gave strong evidence in favour of the theory that dengue fever is carried by a species of *Culex*. Thus mosquitoes have now been incriminated as the carrying agents of no less than four important diseases of man. But this is by no means all. I have mentioned that Bruce incriminated *Glossina morsitans* as the carrying agent of nagana; and he and others now showed that the deadly sleeping sickness of Africa is carried by other tsetse flies. Various Spirochætes, especially that of tick fever, have been shown to be conveyed by ticks. A peculiar type of comparatively mild fever, of which the cause, like that of yellow fever, is still unknown, has been proved to be conveyed by sand flies. Several diseases of animals have been proved to possess a similar history; and others, both of animals and men, are suspected to lie in the same category. Perhaps, however, the most important and dramatic result was that obtained in the case of plague—the most terrible of epidemic diseases, the wonder and the despair of humanity since the beginnings of history, the scourge which was so often attributed to the direct action of God. It is caused really by the rat-flea. And this discovery signals another advance, because plague is, as we all know, due not to an animal but to a vegetable parasite; and we therefore see that bacteria also may adopt precise routes of entry. A similar case is that of Mediterranean fever, which is carried principally by the milk of infected goats; and leprosy (another supposed scourge of Heaven) has been attributed to the bites of bed-bugs; while some are even beginning to think that measles is due to fleas.

CONCLUDING REMARKS.

Gentlemen, I have now completed my task. We have seen at least another instance of how strongly recent advances in science bear upon medicine—how they confirm facts previously guessed at, achieve victories formerly undreamed of, and establish great theorems which will be of value to humanity as long as civilisation exists. But they affect not only the theory and the treatment of disease, but, what is perhaps still more important, its prevention; and it is especially in this line that the new theorems affect us. A whole great epidemiological group of diseases has been separated out—the so-called insect-borne diseases—and they are perhaps on the whole the most important, at least in the tropics. But, more than that, these discoveries give us practical methods of prevention, which may be summed up in two words—No vermin. We now have a great sanitary ideal put before us—so to manage our habitations, villages, towns, and cities that the vermin in them shall be reduced to the lowest possible figure. Scores of entomologists and medical men are now dealing exactly with the habits of these creatures and showing us how to effect the required object. It demands only intelligence, energy, and organisation on the part of administrators. Unfortunately these qualities are not always forthcoming, and administration often lags years behind the dictates of science. Although 15 years have elapsed since many of the facts which I have described were discovered, I think that I may say after constant study of the subject and with all due consideration that mankind has hitherto not effected more than about one-tenth of the improvement of health which it might have effected already if it had put its heart into the business. When I had completed my work in 1899 I had fondly dreamed that a few years would see the almost complete banishment of malaria from the principal towns and cities in the tropics—that those benign climates and those beautiful scenes would be almost rid at once of a scourge which had blighted them from time immemorial. In this I have been disappointed. True, much has been done in certain places, as in Panama, Ismailia, Italy, West Africa, and parts of India and the Malay States, and in some other spots; but much more might have been done had we remained fully alive to our opportunities—and our duties. It is not the fault of science that we do not fully utilise the gifts which she gives to us. None of us here will live to see the full fruition of these gifts in this particular case; but we have at least seen the beginning and may believe that our children will reap the profit.

But it is ever thus with science. Her slaves are like labourers condemned to drive tunnels through mountains—working, perhaps for years, in darkness and oppressed by the immense spissitudes of nature above them, but always encouraged by the hope that at any moment they may emerge into the sunlight and upon the vision of a new world. May I conclude, as appropriate to the subject of this address, with four lines which were written years ago by one who was then toiling at the researches here described and in the darkness of the most utter failure—at work, moreover, for which he had little liking or ambition. They may encourage others who are now in a like case. Writing generally of the sublime spirit of inquiry he said:—

Thee most we honour, thee
  Great Science. Hold thy way.
The end thou canst not see;
  But in the end, the day.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Oct. 22nd, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward. The patient suffering from attacks of faintness, from rupture of the perineum, and the placenta and membranes not having been expelled within two hours of the confinement, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 19. The midwife being unable to make use of a clinical thermometer or to take the pulse of her patients, consequently cannot comply with Rule E. 13. Neglect to employ the antiseptic precautions required by Rules E. 3 and 7, to wash the patient as required by Rule E. 7, and neglect to take the pulse or temperature of the patient as required by Rule E. 13. Discontinuing attendance at a time when the patient was ill and suffering. Not being scrupulously clean in person, clothing, house, and appliances as required by Rule E. 1; not keeping the register of cases as required by Rule E. 23. Medical aid having been sought for the patient, the midwife neglected to send any notification thereof to the local supervising authority, as required by Rule E. 21 (1) (a).

THE WOUNDED IN THE WAR: SOME SURGICAL LESSONS.

BY D'ARCY POWER, M.B. OXON., F.R.C.S. ENG.,
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; LIEUTENANT-COLONEL R.A.M.C. (T.F.), ATTACHED TO THE 1ST LONDON GENERAL HOSPITAL.

IT is still too early to generalise upon the surgical methods needed by those wounded in the present war. It may, however, prove useful to present a few of the results which have been observed in a base hospital in London. As might have been expected, the final results of wounds were seen before the earlier ones, because at first the injured remained in the stationary hospitals until they were well enough to travel. Now that these hospitals are full, and the fighting is often nearer England than the Allies' bases, the type of wound is becoming more serious. Taking the cases in this reverse order, then, we learnt at first that bullets, and even pieces of shrapnel casing, often passed through fleshy parts without doing much damage. The points of entry and of exit were clearly seen. Both had healed satisfactorily, and nothing remained to be done except to feed and nurse the patient for a few days before he was discharged into a convalescent home. In other cases the wounds of entry and exit were suppurating, but the track which must have existed between the two was soundly healed. No sinus remained, and so far it has not been necessary to lay open any such track. It seems clear, therefore, that the most frequent sources of infection are the skin of the patient or some subsequent contamination. It is certainly not due to the clothing, for in several cases pieces of shirt or puttee were removed from wounds which had healed soundly and which had been reopened on account of the pain they had caused. The positions of the wounds of entrance and exit showed in many cases that the path taken by the projectile had been extraordinarily devious, and that the deviation was not accounted for by the presence of any more resistant structure such as bone.

Cases with Foreign Bodies in situ.

The wounds which were still open when the patient reached England were all submitted to radiographic examination on the assumption that the foreign body causing them was *in situ*, and in the majority of cases this was found to be correct. It was soon learnt, however, that there was a vast difference between the location of the projectile and its removal. The radiograph showed its presence, but it was often extremely difficult and might be impossible to find it. The patient, therefore, was told that the wound would be explored, not that the projectile would be extracted. The difficulty lies in the fact that the patients are strong muscular men, and that the shadow only gives an approximate idea of the position and depth of the projectile. It is of the utmost importance therefore that the apparatus as well as the X ray operator should be of first-rate quality. Very little constitutional disturbance was produced, even when the projectile had been in position for three or four weeks, and there was none of the tracking or burrowing of suppurating sinuses which might have been expected. Pieces of the clothing, either in shreds or torn into filaments, were found distally in nearly every case. They had to be looked for, as they were often separated by a bridge of healthy tissue. In some cases where the skiagram showed that the bullet had been extensively comminuted and numerous fragments were distributed widely in the tissues it was thought better to leave them untouched if they were not causing any trouble. In like manner no extensive operations were undertaken to remove foreign bodies from the chest. By the time the patients arrived in England the wounds had healed—apparently without suppuration. When one side of the chest contained fluid it was treated as an empyema by drawing off the blood-stained serous exudation, a portion of rib being removed and drainage employed if the temperature rose or the pleural cavity refilled. It was noticed that most of the operations undertaken for the removal of bullets suppurated for a few days but never dangerously. The operations were performed with the usual precautions and were nursed in the wards by fully trained hospital nurses, so that the suppuration was not attributable to any failure of surgical or nursing technique. It was soon considered advisable, therefore, to isolate patients requiring such "clean" operations as removal of torn internal semilunar cartilages and after this precaution these cases uniformly did well. Amputations at this period were rare and there were no deaths.

Severer Cases.—"Nerve Concussion."

The cases have become more severe as the battles were fought nearer England. Gangrene due to an anaerobic organism has occurred in several cases. Early operation has been performed with success, and the very great value of a free application of a 2½ to 3 per cent. solution of iodine in rectified spirit has been determined. It should be applied to the raw surface of the flaps at the time of amputation, and care should be taken to allow of free drainage by not putting in too many sutures. A few cases of tetanus with a long incubation period have occurred, but the majority of the patients affected with this terrible disease have not come under our care, as they have been treated at the stationary hospitals.

It is almost a matter of common knowledge that the size of the skin wound bears no relation to the severity of the injury. The lower jaw in one case was found to be so comminuted that it had to be removed with a Volkmann's spoon, yet the skin wound hardly admitted a probe, and the patient merely said that he thought his jaw was broken in two places. It is necessary, therefore, to make a detailed examination in every case—under an anæsthetic when possible, and with the necessary preparation for an immediate and adequate operation.

The war, too, has revealed an interesting series of cases which for the present must be called "nerve concussion," about the treatment and prognosis of which much has still to be learnt. When they occur in connexion with the spinal cord they may be the result of a blow from a bullet or piece of shell perhaps no nearer than upon the pack which the soldier is carrying. There is no external wound, but the patient becomes paraplegic. Such a condition is analogous to "railway spine," though it is not associated with neurasthenia at least in the early stages which have come under observation at the present time. A similar condition of paralysis without any gross injury has been noticed in the arms and legs apparently due to interference with the function of one or more nerve trunks, since exposure of the nerve does not show that it has been anatomically damaged. It is too soon yet to state whether recovery of function is the rule or the exception in these cases.

The mental state of the patient makes no difference to the rate of recovery. The English soldier, who is naturally sanguine, heals quickly in spite of suppuration; the Belgian is not far behind, though he is a prey to anxiety, because he grieves for his country, has lost sight of his relatives, and is in hospital in a foreign though friendly land. Like a brave fellow he bears himself in sickness as he does in health with magnificent courage.

Surgical Methods.

The net result of the work appears to show that as in ordinary civil practice meddlesome surgery is generally bad surgery. Wounds need no longer be probed, drained, and packed. Tempered with discretion, it is better to wait than to operate unless the patient is losing ground. Considerable experience, however, is required to decide when to wait and when to operate, because injuries which appear slight superficially may conceal conditions that demand immediate treatment. Looking to the fact that the chief infection seems to come from the patient's own skin, there can be no doubt that antiseptic surgery is preferable to aseptic methods. Dry dressings must give place to compresses and fomentations wherever possible. Iodine applications seem to be more effective than the solutions of perchloride and biniodide of mercury which have been hitherto the more generally used. The youth and health of the patients render the prognosis even of severe injuries correspondingly good and enable the surgeon to take waiting risks which might otherwise be thought hazardous. It is better, therefore, to err on the conservative rather than on the radical side of surgery; at any rate, in the earlier stages.

Chandos-street, W.

THE INTRATRACHEAL ADMINISTRATION OF CHLOROFORM.

By W. DAKIN MART, B.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,
ANÆSTHETIST TO THE NOSE, EAR, AND THROAT DEPARTMENT, ROYAL INFIRMARY, SHEFFIELD.

ONE hears nowadays a great deal concerning the intratracheal administration of ether and very little concerning the intratracheal administration of chloroform. I have of late administered chloroform by this method in operations on the nose and throat performed by Mr. W. S. Kerr, honorary surgeon to the Nose, Ear, and Throat Department of the Royal Infirmary, Sheffield, who has expressed his satisfaction with the method.

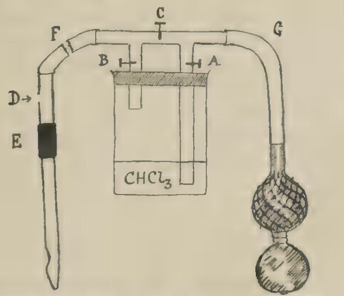

Diagram of apparatus for intratracheal administration of chloroform. A, B, C, Taps. D, Extra opening in catheter. E, Metal collar. F, Long rubber tube (represented broken) to catheter. G, Rubber tube from Junker bellows.

The apparatus used differs from a Junker's inhaler in that there is a cross tube connecting the entry and exit tubes. Each of these tubes carries a tap, A, B, and C (see diagram). When A and B are open and C is closed it acts as an ordinary Junker's inhaler. When A and B are closed and C is open air alone is pumped into the lungs—in fact, "artificial respiration" can be performed. To this so modified apparatus a catheter is attached, which carries the chloroform vapour to the trachea. The catheter I have used is a gum elastic No. 12, but differs in two respects from an ordinary catheter. 1. There is an additional opening, D, of the same size as the eye, which opening is situated in such a position that when the catheter has been properly introduced it is outside the patient's mouth, and through which the patient can breathe. 2. Surrounding the catheter is a thin metal tube, E, which is situated in such a position that the patient's teeth are prevented from injuring the catheter. The length of this tube is about 1½ inches.

Method of administration.—The patient is first of all anæsthetised by chloroform sprinkled on a mask in the ordinary way; then before he is quite fully under the influence of the anæsthetic the upper part of the larynx is swabbed with 10 per cent. cocaine, and when quite under the catheter is introduced into the larynx by means of a bronchoscope and attached to the rubber tube connecting with the modified Junker inhaler. The introduction of the catheter into the larynx is rather liable to give rise to coughing unless the patient is fully under the influence of the anæsthetic. The middle finger of the left hand is then placed over the opening in the catheter, which is, as I have mentioned above, situated just outside the patient's lips, and then the right hand compresses the Junker bellows three times. The finger is then removed from the catheter opening, through which the patient is now allowed to take two or three breaths. If the patient has partially come round the chloroform vapour so pumped into the lungs is liable to excite coughing, which, however, ceases on the removal of the finger from the catheter opening and when two or three breaths have been taken by the patient. Then again cover up the opening and try two compressions and again remove the finger letting the patient breathe once, and so on, suitably varying the amount of chloroform and air until the patient is completely anæsthetised. This being accomplished, the assistant places a sponge, to which is attached a silk thread, at the back of the throat around the catheter. This, while preventing the entry of blood into the larynx, is not packed so tightly as to maintain a dangerous pressure in the lungs. One is unable to do this in intratracheal administration of ether, and as a consequence blood has a tendency to enter the larynx in operations on the nose and throat—not only has a tendency, but actually does do so, for when administering ether by the intratracheal method I have found blood in the eye of the catheter in a case where all possibility of traumatism was excluded.

During the continuation of the anæsthetic I usually compress the Junker bellows not more than four times in succession and then allow two or three breaths of air through the catheter opening, the number of breaths allowed depending naturally upon the degree of narcosis to which the patient has attained. I have found nothing to indicate that the pressure obtained in the lungs by four compressions of the Junker bellows is other than a safe one.

When the operation is nearly at an end I frequently cut out the chloroform vapour altogether by closing taps A and B and opening tap C (see diagram), and then on compressing the bellows and closing the catheter opening air is pumped into the lungs. In one case in which this was done, and in which the operation had lasted one hour, the patient was quite rational half an hour afterwards. I think this fact of being able to pump air into the lungs should be very valuable in those cases where there is a sudden cessation of respiration due to excess of chloroform, but of this I am fortunately unable to speak from experience.

I have been told that the intratracheal administration of chloroform is dangerous, but so far I have not found it so, the anæsthesia being very light and the control of the patient good—in fact, it is difficult to get the patient deeply under, and unless the throat is plugged round the catheter, as described above, the tendency is for the patient to show signs of returning consciousness. Should the operation be one in which there is no danger of blood entering the lungs, then it is not really necessary to have an external opening in the catheter, as there is sufficient space around the catheter for respiration.

The advantages of the method are: 1. The simplicity of the apparatus. 2. The easy portability. 3. The prevention of blood entering the lungs. 4. The fact of being able to give artificial respiration with the same apparatus. 5. Less hæmorrhage takes place than is the case when ether is given in operations about the nose and throat.

Now it has been maintained by some that the use of adrenalin in conjunction with chloroform is liable to lead to grave results; the fact that I have experienced none such may be taken as an additional indication of the safety of the method.

The following are cases in which the method has been used:—

1.	Male	aged	50.	Right Denker's operation.
2.	Male	,,	23.	Double Coldwell Lac operation and exploration of sphenoidal sinus.
3.	Female	,,	17.	Canfield Ballenger's operation.
4.	Male	,,	36.	Septal spur removal, intranasal antral operation.
5.	Female	,,	17.	Tumour of upper jaw (osteo-fibroma).
6.	Male	,,	18.	Removal of outer walls of inferior meatuses.
7.	Male	,,	24.	Submucous resection and exploration of antrum.
8.	Male	,,	20.	Submucous resection and Canfield Ballenger's operation.
9.	Male	,,	51.	Canfield Ballenger's operation.
10.	Male	,,	34.	Canfield Ballenger's operation.
11.	Male	,,	45.	Canfield Ballenger's operation.
12.	Male	,,	23.	Submucous resection.
13.	Male	,,	25.	Canfield Ballenger's operation.
14.	Male	,,	19.	Œsophagoscopy.
15.	Male	,,	21.	Double maxillary sinus operation and nasal polypi.
16.	Male	,,	65.	Pharyngectomy. Post mortem, lungs normal.

Case 14 was of interest in that the patient was an imbecile. He had an enlarged tongue, also swelling of the arytenoids, interarytenoid region, false cords, and the lower part of the pharynx. He was anæsthetised first of all by chloroform sprinkled on a mask. When the œsophagoscope was introduced it was found that such marked obstruction to respiration was caused that the operator was forced to desist. The intratracheal catheter was then introduced and anæsthesia proceeded with by the above-described method. The œsophagoscopy was now continued without the slightest trouble, the patient breathing quite easily through the catheter. Mr. Kerr, the operating surgeon, considered that the œsophagoscopy would have been impossible unless this method of anæsthesia had been adopted.

Case 16 was one of carcinoma, death taking place about a week after the operation. At the necropsy the lungs did not show any signs of damage due to excessive pressure.

In preparing this paper my thanks are due to Mr. Kerr for much help and suggestion; to Mr. Stevenson, house surgeon to the Nose, Ear, and Throat Department; and to the Medical Supply Association for making all the apparatus used.

Sheffield.

ETHER ANÆSTHESIA BY THE INTRATRACHEAL METHOD: A REPORT ON 49 CASES.

BY RUPERT LLEWELLYN JONES, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON TO THE BRISTOL GENERAL HOSPITAL.

IN November, 1913, Dr. F. E. Shipway, of Guy's Hospital, visited Bristol and gave a demonstration of positive pressure ether anæsthesia in the theatre of the General Hospital. The subjects, by his kind permission, form Nos. 1 and 49 of our series.

The Apparatus.

The apparatus used by Dr. Shipway was that which he describes in the first number of the *British Journal of Surgery*. The expense of this outfit for a method of anæsthesia which is as yet barely past the experimental stage and which is not designed for universal application, made it necessary for us to improvise a cheap and simple plant which we could use until we were satisfied that more elaborate apparatus was justified. The air was delivered to the ether chamber of our apparatus through rubber tubing by a simple force-pump driven by an electric motor. The ether chamber was arranged on the surface-evaporation principle, no bubbling through being provided for. By means of a two-way tap the amount of air deflected into the ether chamber could be varied from "none" to 100 per cent. This ether chamber held about a pint of ether and the evaporating surface had a diameter of 5 inches. From this chamber the mixture was carried to the warming chamber and passed through a lead spiral. A T-piece of glass tubing was interposed between the warming chamber and the patient. The stem of the T led nearly to the bottom of a column of water 8 inches long; so that when the pressure in the patient's lungs reached 8 inches of water, air bubbled from the stem of the T-piece and a safety-valve action was set up. As a stand-by in case the force pump failed, we used a large foot bellows and rubber bag reservoir. To intubate the larynx we used gum-elastic catheters with straight extremities, stiffened by the incorporation of a stilette. They were introduced by the direct vision method by means of Hill's instrument.

Technique.

All the patients above 18 years of age had, one hour before the operation, a subcutaneous injection of hyoscine hydrobromide, gr. 1/100; morphine sulphate, gr. 1/6; and atropine sulphate, gr. 1/100. Some of our first cases had the area of the larynx painted with a 5 per cent. solution of cocaine, but we early discontinued the practice as a routine procedure, for we found that a reasonable depth of anæsthesia at the time of the intubation was the main factor in controlling the subsequent spasm of the glottis. When the patient was sufficiently anæsthetised by the inhalation method the anæsthetist opened the mouth with a gag introduced from the left side. The operator standing on the right side of the patient introduced the laryngoscope and lamp. The gag was then withdrawn, as the widely opened mouth tended to push backwards the base of the tongue, rendering the rima glottidis unnecessarily inaccessible. On obtaining a clear view the operator introduced the catheter and withdrew the laryngoscope and stilette. Glottic spasm and coughing usually followed the catheterisation of the larynx. To prevent the patient's biting the catheter a wooden prop resembling a cotton reel was slipped along the catheter until it lay between the teeth. The pump was then started and the rubber tube from the apparatus connected to the catheter. The patient usually passed fairly rapidly into the typical condition of quiet anæsthesia. At the finish of the operation the ether chamber was cut out and the patient supplied with pure air until a brisk corneal reflex was present. The catheter was then removed and natural respiration followed.

The main points which exercised us at different times were: 1. Our force pump was very noisy and delivered its air in a series of puffs. 2. A few cases could not be sufficiently deeply anæsthetised (Nos. 27 and 31), probably owing to the small size of the ether chamber and rubber tubing of too narrow a bore. 3. The water valve was very sensitive and was ideal so long as the respirations were quiet, but was apt to bubble and splash when coughing occurred. 4. The catheterisation of the larynx by the direct method is a manœuvre requiring practice and a definite amount of dexterity, so that in our cases the surgeon was nearly always responsible for its successful conduct. This, of course, made for delay in the commencement of the operation. When anæsthetised the appearance was, as Shipway says, that of a person asleep. The colour was practically always good—often better than when the patient took his place upon the table. The respirations were light and regular, the pulse good, and the corneal reflex absent or just present. The regularity of the supply of anæsthetic allowed of a lighter degree of anæsthesia than with the inhalation methods. The experiments of Janeway and Ewing would suggest that a method of anæsthesia which reduces the respiratory excursions to a minimum would be of value in reducing shock.

Review of the Cases.

Our early attempts at catheterising the larynx were prolonged and the results of slight trauma were sometimes apparent. Our inquiries regarding sore throat were sometimes answered in the affirmative and pain on swallowing complained of. In Case 8 one of the lateral incisors of the upper jaw was knocked out and the lower lip lacerated. This was the only case where a definite lesion was inflicted.

The question of subsequent pulmonary trouble claimed our attention. Our first case, upon which Dr. Shipway demonstrated, suffered from a severe tracheitis and coughed up quantities of stringy mucus. The fact that the method is not a guarantee against pneumonia is suggested by Case 7, in which death occurred, owing to this complication, a week after the operation. On the other hand, Case 36 had definite signs of pleurisy at the right base, which were not aggravated by the anæsthetic and which disappeared in the course of an uneventful convalescence. Two others had slight coughs after their operations, but there was no rise of temperature. We found that the ease—or the reverse—with which the catheter could be passed into the larynx differed very greatly in individuals. The thick-necked type of patient offered considerable difficulty, so also did cases of goitre, whilst any infiltration of the base of the tongue, as in epithelioma, was also an obstacle. In operations on the mouth, throat, and nose the method compares favourably with the inhalation method, the necessity for hurry, with its associated bustle, being eliminated.

All the following cases, with the exception of Cases 16 and 49, were under the care of Mr. Hey Groves, who designed the apparatus used, and to whom I am indebted for permission to publish this paper. My thanks are due to Dr. Poole Lansdown and Mr. J. Lacy Firth for permission to report their cases.

Brief Notes of the 49 Cases.

CASE 1.—A male aged 30. Chronic empyema with left cord paralysis. Hyoscine. 5 per cent. cocaine to larynx. Intubation of larynx was successful at the first attempt. The patient breathed badly; there were coughing and dyspnœa. He had dyspnœa afterwards and orthopnœa. Ten days after operation he discharged himself unrelieved, and died two weeks later. At the necropsy enlarged mediastinal glands were found, apparently sarcomatous.

CASE 2.—A male aged 30. Sinus of thigh. Hyoscine. No cocaine. Catheterisation was effected after repeated attempts. Anæsthesia was satisfactory. The patient complained of stiffness of the throat next day, which passed off.

CASE 3.—A male aged 21. Inguinal hernia. Hyoscine. No cocaine. Catheterisation was effected at the fourth attempt. Anæsthesia was typical and satisfactory. There was transient soreness of the throat next day.

CASE 4.—A male aged 12. Tonsils and adenoids. No hyoscine. No cocaine. Catheter was easily introduced at first attempt. Anæsthesia was quiet and moderately deep. The tonsils were dissected piecemeal to the accompaniment of free hæmorrhage. Convalescence was uneventful.

CASE 5.—A female aged 67. Gall-stones. Hyoscine. No cocaine. This patient was of the thick-necked type and attempts to introduce a catheter with Hill's speculum failed repeatedly. Catheterisation was ultimately effected by the digital method. Anæsthesia was typical. Transient sore throat was present next day.

CASE 6.—A female aged 17. Goitre. No exophthalmos or tachycardia. Hyoscine. No cocaine. Prolonged and repeated attempts at catheterisation failed and the operation was finished under anæsthesia by the inhalation method.

CASE 7.—A male aged 52. Epithelioma of tongue. There was a large and foul ulcer. Hyoscine and cocaine were given. The operation, including removal of the glands, took 70 minutes. The catheter was passed without difficulty. Typical quiet anæsthesia. Four days after the operation the patient developed signs of pneumonia at the right base and died a week after his operation.

CASE 8.—A male aged 15. Suppuration in an appendix wound with signs of ileus. No hyoscine or cocaine. Catheterisation took five minutes. Typical anæsthesia. An upper incisor was knocked out and the lip lacerated during the process of catheterisation. The patient made a good recovery.

CASE 9.—A male aged 43. Double inguinal hernia. Hyoscine given. No cocaine. Introduction took eight minutes. Anæsthesia was continued with the foot bellows, which were found to be inadequate. During the preparation of the motor the catheter slipped out and the operation was finished by the inhalation method.

CASE 10.—A male aged 21. Sinus of thigh. Hyoscine. No cocaine. Introduction took two minutes. Anæsthesia was light but sufficient. No subsequent sore throat was noticed.

CASE 11.—A male aged 28. Tuberculous pyopneumothorax. Hyoscine and cocaine. Introduction took two minutes. The patient remained a good colour but coughed frequently throughout the operation. Sinuses explored and found to lead into the mediastinum. No subsequent sore throat. The cough did not appear aggravated.

CASE 12.—A male aged 48. Hydrocele. Chronic bronchitis. Hyoscine and cocaine. Catheter introduced at first attempt. Colour remained excellent throughout the operation. The cough was not aggravated.

CASE 13.—A male aged 27. Hæmorrhoids. Hyoscine and cocaine. Catheter introduced easily. The patient did not resent stretching of the sphincter. No subsequent cough or sore throat.

CASE 14.—A male aged 52. Enlarged prostate. Hyoscine and cocaine. Catheter introduced at first attempt. Immediately afterwards the pulse became weak but improved again. Suprapubic prostatectomy was performed. Anæsthesia was light, quiet, and adequate. No subsequent sore throat or cough.

CASE 15.—A male aged 13. Osteomyelitis of foot. No hyoscine. Cocaine. Intubated at second attempt—there was considerable laryngeal spasm. A reflex was present at the commencement of the operation, but quickly disappeared. No sore throat was noticed afterwards.

CASE 16.—A male aged 55. Epithelioma of tongue. (Mr. J. L. Firth's case.) Intubation was tried repeatedly for 30 minutes, but unsuccessfully owing to infiltration of the base of the tongue. Œdema of the uvula supervened during the operation, which was performed under chloroform administered through a laryngotomy opening. The patient died suddenly 28 hours later from heart failure.

CASE 17.—A female aged 18. Duodenal ulcer. Hyoscine and cocaine. Intubation was effected at the first attempt. The anæsthesia was uneventful; the patient remained a good colour and breathed quietly. Convalescence was uneventful.

CASE 18.—A male aged 48. Exostosis of femur. Hyoscine and cocaine. Intubation without difficulty. Anæsthesia typical and uneventful. No subsequent trouble.

CASE 19.—A male aged 50. Recurrent paroxysmal vesical pains with frequency of micturition, for which no cause could be found. Hyoscine. No cocaine. Intubation successful at first attempt. Typical anæsthesia. The spinal cord was exposed and a number of posterior nerve roots divided. No subsequent sore throat.

CASE 20.—A male aged 36. Hernia. Hyoscine. No cocaine. The patient was of the thick-necked type and intubation took 10 minutes. Typical quiet anæsthesia. No sore throat or cough subsequently.

CASE 21.—A male aged 56. Exploration of suprapubic wound. Hyoscine. No cocaine. Intubation easily effected. Typical uneventful anæsthesia. No subsequent trouble.

CASE 22.—A male aged 50. Cerebellar tumour. Decompression operation. Intubation took five minutes. The patient was then turned on his face and anæsthetic was continued for 20 minutes very successfully. The catheter then fell out and inhalation was resorted to. There was a little cough at night afterwards, which passed away quickly.

CASE 23.—A female aged 45. Hæmorrhoids. Hyoscine. No cocaine. Intubation took five minutes. Typical quiet anæsthesia. No reflex on dilating sphincter. No unpleasant after-effects.

CASE 24.—A female aged 34. Hysterical contractures of legs. Hyoscine. No cocaine. Intubation took five minutes. Quiet anæsthesia. No subsequent sore throat. This patient during a previous anæsthetic with a chloroform mixture had caused some anxiety as regards her pulse and respirations.

CASE 25.—A male aged 23. Hernia. Hyoscine. Catheter introduced easily. Typical anæsthesia. This patient said that his throat was a little sore after the operation, but "not to trouble him."

CASE 26.—A female aged 29. Gastric ulcer. Hyoscine and cocaine. Intubation easily effected. Light but adequate anæsthesia. Gastro-enterostomy was performed. Convalescence uneventful.

CASE 27.—A male aged 47. Duodenal ulcer. Hyoscine. No cocaine. Intubation successful at second attempt.

Sufficiently deep anæsthesia could not be obtained; a brisk reflex following any attempt to proceed with the operation. The inhalation method was resorted to. On recovering from the anæsthetic the patient had a slight cough which he had not noticed before.

CASE 28.—A male aged 52. Catheterisation. Hyoscine. No cocaine. Intubated at first attempt. Typical anæsthesia. No sore throat.

CASE 29.—A male aged 39. Hernia. Hyoscine. No cocaine. Intubation took eight minutes; the patient was thick-necked. Adequate anæsthesia. He said that his throat was sore after the operation; there was some pain on swallowing.

CASE 30.—A male aged 26. Hernia. Hyoscine. No cocaine. Catheter was introduced at first attempt. Typical anæsthesia. There was a little soreness of the throat. Two days after the operation a loose cough developed which got slowly better.

CASE 31.—A male aged 40. Stricture. Perineal section. This patient had neither hyoscine nor cocaine. The introduction of the catheter took seven minutes. The anæsthesia was not good; there was a brisk reflex which could not be diminished, and it was necessary to resort to the inhalation method before the operation could be proceeded with. There was no subsequent sore throat or cough.

CASE 32.—A female aged 45. Laparotomy. Hyoscine. No cocaine. Intubation was effected at the first attempt. Typical anæsthesia throughout the operation. No after-effects.

CASE 33.—A male aged 15. Appendix abscess. No hyoscine. No cocaine. Intubation successful at first attempt. Typical uneventful anæsthesia. The patient vomited for 36 hours.

CASE 34.—A female aged 33. Femoral hernia. Hyoscine. No cocaine. Larynx was intubated at first attempt. Typical anæsthesia without after-effects.

CASE 35.—A male aged 46. Gastric ulcer. Hyoscine. No cocaine. Catheter introduced without difficulty. The patient soon passed into a condition of quiet typical anæsthesia. No subsequent sore throat or cough.

CASE 36.—A female aged 38. Appendix abscess. This patient had signs of involvement of the base of the right lung in the shape of dulness and diminution of the breath sounds. The respirations were increased to 27–30. The temperature was normal. Hyoscine was given but no cocaine. Larynx was catheterised without delay. Typical quiet anæsthesia was soon obtained. There was a troublesome cough at night after the operation, but it slowly got better.

CASE 37.—A male aged 21. Ventral hernia in appendix scar. Hyoscine. No cocaine. Larynx was easily catheterised. This was the one case in the series where it was found necessary to diminish the supply of ether owing to the depth of anæsthesia induced.

CASE 38.—A male aged 28. Sciatica. Hyoscine. No cocaine. Catheter easily introduced with the patient on his side. The anæsthetic was continued with the patient lying on his face. The sciatic nerve was exposed, stretched, and injected with novocaine. There was a brisk reflex at first, and a tendency to resent the manipulations was present throughout the operation.

CASE 39.—A male aged 54. Fractured humerus—amputation. Hyoscine. No cocaine. Intubation successful at first attempt. Typical anæsthesia. No cough or sore throat.

CASE 40.—A female aged 36. Double inguinal hernia. Hyoscine. No cocaine. Catheterisation of larynx took ten minutes and was successful at the third attempt. The patient then passed rapidly into the typical condition of anæsthesia. There was no subsequent sore throat.

CASE 41.—A male aged 35. Perforated duodenal ulcer. No hyoscine. No cocaine. Larynx catheterised at first attempt. Typical quiet anæsthesia, whilst ulcer was sewn over. Uneventful convalescence.

CASE 42.—A female aged 21. Cerebellar tumour, preliminary decompression. Hyoscine. No cocaine. Larynx was catheterised without difficulty and the patient was turned on her face, in which position the anæsthetic proceeded quietly. There was severe hæmorrhage from the scalp and the patient became pulseless. On turning the patient over at the end of the operation there was no sign of life, and the usual treatment failed to resuscitate her.

CASE 43.—A male aged 35. Hernia and varicocele. Hyoscine. No cocaine. Larynx was catheterised with ease. Typical quiet anæsthesia. No after-effects.

CASE 44.—A male aged 5 weeks. Hare-lip and cleft palate. No hyoscine. No cocaine. Great difficulty was experienced in introducing a narrow black rubber catheter into the larynx. The ordinary method was quite unsuccessful, but after several attempts the larynx was catheterised through a small urethral speculum. A glass funnel was attached to the end of the catheter, and gauze on which was dropped chloroform, placed inside; but the patient could not be kept anæsthetised and we had to resort to Junker's inhaler. The hare-lip was repaired. There was no cough subsequently.

CASE 45.—A female aged 31. Appendicitis. Hyoscine. No cocaine. Catheterisation of larynx effected at first attempt. Typical anæsthesia. No subsequent cough or sore throat.

CASE 46.—A female aged 24. Tuberculous knee. Arthrectomy and wiring, medullary peg. Hyoscine. No cocaine. Catheterisation of larynx presented no difficulty. This patient passed into a condition of deep anæsthesia and was pale, but otherwise gave no trouble. There were no after-effects.

CASE 47.—A female aged 19. Necrosis of jaw. Hyoscine. No cocaine. Intubation at second attempt. Quiet anæsthesia whilst manipulations inside the mouth were in progress. No after-effects.

CASE 48.—A male aged 37. Tuberculous sinus of back. Hyoscine. No cocaine. Larynx catheterised at first attempt. Typical anæsthesia. No after-effects.

CASE 49.—A male aged 58. Hernia and hydrocele (Mr. Lansdown's case). Hyoscine and cocaine. Anæsthetic conducted by Dr. Shipway. Catheterisation was easily effected. Typical quiet anæsthesia. No after-effects.

St. Austell, Cornwall.

ACCESSORY SPLEEN CAUSING ACUTE ATTACKS OF ABDOMINAL PAIN.

BY R. C. ALEXANDER, M.B., CH.B. EDIN.,
F.R.C.S. EDIN.,
TUTOR IN CLINICAL SURGERY, ROYAL INFIRMARY, EDINBURGH
ASSISTANT TO THE PROFESSOR OF SURGERY, UNIVERSITY
OF EDINBURGH;
AND
ARCHIBALD ROMANES, M.A., M.B., CH.B. EDIN.,
LATE HOUSE SURGEON, ROYAL INFIRMARY, EDINBURGH.

THE frequency with which the pathologist meets with accessory spleens at necropsies makes it rather remarkable that their presence is rarely noted by the operating surgeon. Adami and Nicolls[1] state that they are found at 11 per cent. of all necropsies and that they may reach the size of a walnut. Shennan[2] states that they are "frequently found." Their situation varies. They may lie in the gastro-hepatic or gastro-colic omenta, or even in the stomach wall itself. On consulting various standard text-books on surgery we have found their occurrence noted once only,[3] and that merely as an anatomical fact, and not because their presence had any pathological significance. Rocher[4] states that he has frequently at operations observed the occurrence of accessory spleens, especially in young subjects. On examination of bodies in the post-mortem room he found that those seen in the infant were in many

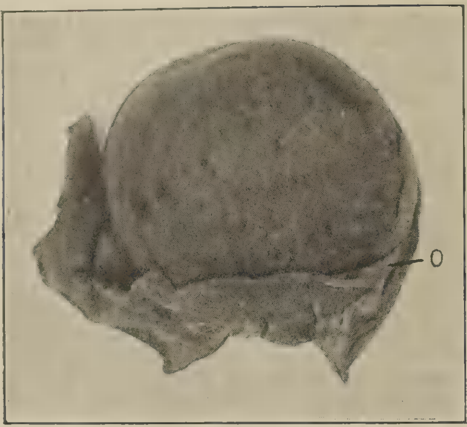
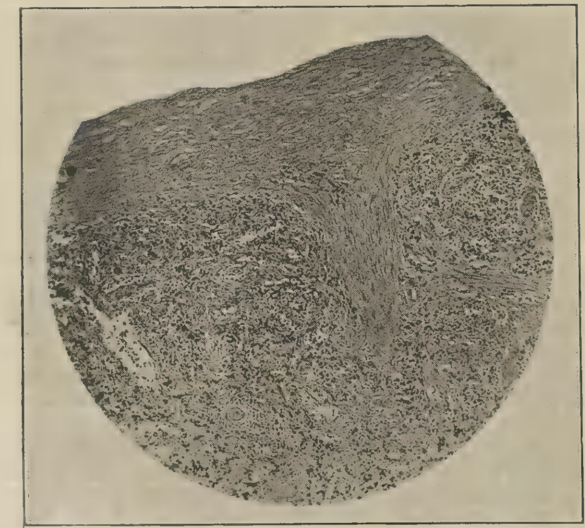
cases undergoing atrophy, and that the splenic tissue was difficult to recognise. These were less red than the others, almost yellow, and "of a faded appearance." On the contrary, those of a red colour showed the normal structure of the spleen. From the diminished frequency of their occurrence in the adult he thinks these accessory organs show a tendency to disappear with age. Two, four, or seven of these organs were most commonly met with in each case, but Orth records 400 in one instance. Their situation Rocher has noted post mortem "at the hilum of the spleen, in the gastro-splenic omentum, in the pancreatico-splenic ligament, and in the great omentum." They may be sessile or pedunculated, and in the latter case several smaller ones are often found in the pedicle of a larger one—"disposition en chapelet." Their shape is spherical, oval, or pyriform. This author ascribes their distribution to their development in the dorsal mesentery, and especially that segment from which the stomach and pancreas are formed. He appears to regard them as portions of the normal organ which have been separated during development.

FIG. 1.



From a photograph of the accessory spleen with omentum (O) reflected. Natural size.

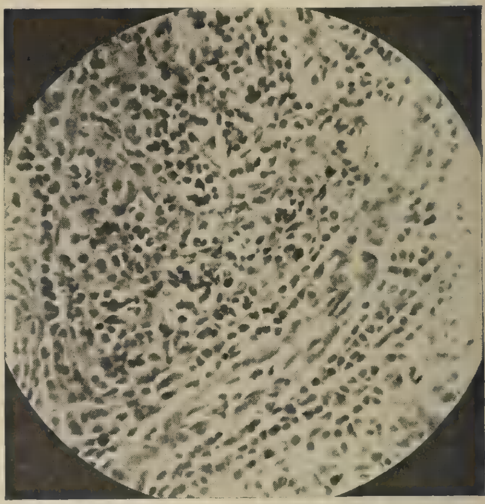
FIG. 2.



From a photomicrograph of the accessory spleen; low power.

Albrecht, of Vienna, quoted by Osler and Macrae,[5] reports a case in which "an enormous number of supernumerary spleens was found; in the usual situation was a normal spleen the size of a walnut with the splenic artery and vein in their normal position. The other spleens were scattered not only in the mesogastrium, but also on the peritoneum—as, for example, on the hepatic ligament and on the convexity of the liver; the largest number was found on the mesentery and transverse mesocolon; there were more than 30 in Douglas's pouch. Each of these spleens was enclosed in a separate capsule covered by peritoneum and exhibited the gross microscopic structure of splenic tissue." Warthin suggests that this is not simply a congenital condition, but rather a compensatory process of accessory spleen development secondary to a congenitally deficient primary spleen or to acquired disease of the spleen. This view seems to us to be borne out by the statement of W. J. Mayo[6] that accessory spleens are found in the pedicle during splenectomy for tumours, &c.

FIG. 3.



From a photomicrograph of the accessory spleen; high power.

The fact of a patient who presented a very definite set of symptoms produced by an accessory spleen coming before our notice induced us to search for other published cases, and we were able to trace but one similar case. We summarise both these cases.

In the case which we ourselves observed the patient was a young woman aged 25, who three years previously had had her right kidney removed for calculous pyonephrosis. A year previously to her admission to hospital she was suffering from an attack of tonsillitis, and while her medical attendant was treating her for that condition she complained of abdominal pain. One of us (R. C. A.) who saw her at that time discovered a mass about the size of a golf ball in the left upper quadrant of the abdomen. This mass could be freely moved about all over the upper abdomen and was somewhat tender to touch. The only other clinical facts of note were a greatly enlarged left kidney, possibly a compensatory hypertrophy, and a considerable degree of albuminuria. A few days later another examination was made, and this time the lump could not be felt until the patient had sat up in bed, when it was easily palpated. She was sent to the surgeon who had previously removed her kidney, but owing to her general health being below par he was unwilling to operate. She returned home and improved in general health, but was subject to frequent attacks of pain of a dragging nature in the upper abdomen, this pain having no relation to the taking of food. The pain was usually rendered worse when the patient stooped, and was unaccompanied by other symptoms. These attacks of pain occurred almost daily, coming on suddenly, lasting for one or two hours, then passing off and leaving her quite well.

---

[5] Osler and Macrae: System of Medicine, 1908.
[6] W. J. Mayo: Surgery, Gynecology, and Obstetrics, March, 1913.

In August, 1912, the patient was admitted to the Royal Infirmary, Edinburgh, under the care of Mr. J. W. Dowden. The lump remained about the same size as formerly, and otherwise, with the exception of the enlargement of the left kidney, nothing abnormal was detected on examination. The spleen was normal in size. Her general health was good, and the amount of albumin in the urine very small. The tentative diagnosis of mesenteric or omental cyst was made, and as the patient said that the pain was exceedingly severe when it occurred and that it was making her miserable, Mr. Dowden decided to explore the abdomen. Under a general anæsthetic an incision was made through the upper part of the left rectus muscle. The viscera appeared normal, and no trace of any tumour could be found till the hand was passed up under the diaphragm on the left side and a rounded mass was felt. This was easily delivered at the wound, and proved to be an accessory spleen about the size of a small tangerine orange situated at the lowest part of the great omentum. There were several large vessels running towards it. The omentum was ligatured and the splenculus, which was entirely surrounded by omentum, was removed. The stump of the omentum was carefully stitched to prevent adhesions forming and the abdomen closed. No other accessory spleens were seen. Convalescence was uninterrupted and the patient had no recurrence of symptoms.

On examination the specimen was a perfect sphere (Fig. 1), and on section it presented a homogeneous appearance. Microscopically its structure resembled that of the spleen, except that the lymphoid follicles were not so well developed and that there was considerable fibrosis of the whole organ with recent and old hæmorrhages (Figs. 2 and 3).

We regard the cause of the pain to have been congestion of the viscus from torsion of the omentum obstructing the return blood flow. There was no necrosis visible and there had been apparently no arterial obstruction.

A similar case has been recorded by Témoin (Hôtel-Dieu, Bourges).[7]

The patient was a woman aged 35 years. There was no previous history of illness except that since the age of 20 she had suffered greatly during her menstrual periods. At the first of these painful periods she thought she felt a swelling in her abdomen associated with some abdominal pain. Three years ago she experienced a renewal of this abdominal pain, and discovered just above the umbilicus almost in the middle line a swelling of the size of a large nut. Since that time she had a suffered from constant pain and impaired digestion, with vomiting of stomach contents and bile. During the past year she had consulted several medical men on account of progressive loss of flesh. She came to Dr. Témoin, who discovered a firm tumour, painless on light palpation, situated in the middle line of the abdomen a little above the umbilicus, and of the size of a Tangerine orange. The tumour was slightly movable. Nothing was done at this time, but five months after the patient returned in worse health than before. She had had attacks like intestinal obstruction, and the tumour had if anything slightly enlarged. The surgeon adhered to his former diagnosis of intestinal tumour and proposed a laparotomy.

Under chloroform an incision was made in the middle line and the abdomen was opened. The tumour was discovered lying beneath the omentum, which was attached to the surface of the tumour. The adhesions seemed firm, but were easily separated, as they consisted only of a few vessels. The tumour came into view with its surface lying closely against a loop of intestine. It seemed to be merely pressed against the gut and not to form part of the wall. With blunt dissection the surgeon was able to isolate the tumour, and soon found it attached only by a few small vessels running to the margin of the mesentery. The tumour was removed, the abdomen closed, and the patient made a rapid recovery. Three months after the operation she was very well with perfect digestion and no pain.

The tumour was of the size of a Tangerine orange, and on section appeared like a healthy spleen. Histology: Pulp in small amount; trabeculæ very thick, containing many calcareous particles; some sclerosis of the organ.

In reporting this case Témoin states that he has failed to find a similar one recorded. He was uncertain at first whether it was a movable spleen, but the symptoms did not correspond, and in all the cases he found recorded the movable spleens were hypertrophied. He therefore decided that it was an accessory organ which by its weight or by pressure had caused the digestive disturbances.

For our own part we are inclined to believe that, as in the first case, a species of volvulus of the organ took place. This resulted in some interference with the mesenteric circulation and in the kinking of the loop of gut to which the splenculus was attached, giving rise to recurrent attacks of pain and vomiting resembling intestinal obstruction.

We are indebted to Mr. Dowden for permission to publish his case, and to Dr. Disney Cran who during a residence in Paris transcribed for us the French references unobtainable in this country.

Edinburgh.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

NOTES OF A CASE OF ACIDOSIS FOLLOWING CLINICAL DIPHTHERIA.

By H. W. HARDING, M.D. LOND., D.P.H.,
ASSISTANT MEDICAL OFFICER OF HEALTH, GREAT YARMOUTH.

THE patient, a female aged 4 years, was received into the Great Yarmouth Isolation Hospital on Oct. 25th, 1912, suffering from clinical diphtheria.

Previous history: Measles only; no attacks of vomiting. On admission: Pallid face, tonsils swollen, the left covered with a large patch of membrane; tongue thickly furred; left submaxillary glands very much enlarged; pulse 120, small; temperature 97·6° F. She received 4000 units of antidiphtheritic serum. Swabs showed presence of Hoffmann's bacillus; Klebs-Löffler bacillus not seen. Oct. 26th: Thick nasal discharge. Nov. 1st: Albuminuria lasting 11 days. 6th: Nasal voice; no regurgitation. 16th: Voice normal; palate moves. 26th: Vomited undigested food. Dec. 3rd: Vomited after liquorice powder; colour good. 4th: Quite well; allowed to get up. 7th: Vomited watery fluid after breakfast; pallid; heart normal; vomited curdled milk at 12, and again after water at 2 P.M. Complained of thirst and headache. 8th: Vomited six times during morning; after that retained water; enema given with constipated result; tongue clean; heart *nil;* knee-jerks present; no albumin. 9th: Vomited 16 times during the day; no abdominal distension or retraction; pulse fair and colour good. Vomit had acid odour, both it and the urine giving the colour reaction with ferric chloride. Enemata of sodium bicarbonate half-drachm doses given every three hours. 10th:

---

[7] Témoin: Archives Provinciales de Chirurgie, Paris, vol. vii., 1898.

No vomiting during the night; enemata given six-hourly; child grew drowsy during latter part of day. 11th: Vomited again at 10 A.M. Takes well of sodium bicarbonate in water. Is fretful. 12th: Vomited once this morning. Still on enemata every six hours, as well as orange juice and sodium bicarbonate by mouth. Put on bovril. 13th: Vomited twice this morning; very torpid; sodium bicarbonate increased; one drachm four-hourly by rectum. whilst the bread-and-butter and milk-pudding was sprinkled with it; making about 1½ oz. in the 24 hours. Vomited once on the 14th and on the 15th; after that date no further nausea, child taking food well and got quite bright mentally. 18th: Enemata omitted, but sodium bicarbonate still added to food. 19th: Sodium bicarbonate reduced to half an ounce in 24 hours. 20th: Very little colour with ferric chloride. 21st: Urine gives no colour with ferric chloride and patient put on fish diet. 28th: Swab gave Hoffmann's bacillus. Jan. 6th: Ready for discharge.

Fortunately the odour of the vomit was marked, or else the sickness might have been thought to be of vagal origin. The torpid condition of the child was not, however, that associated with the latter, and appeared rather a characteristic symptom; it improved rapidly with the increased doses of sodium bicarbonate; this latter was reduced as soon as effervescence was given with ferric chloride and the urine.

Great Yarmouth.

NOTES OF A CASE OF EXTENSIVE SURGICAL EMPHYSEMA.

BY E. NORMAN BUTLER, M.R.C.S. ENG., L.R.C.P. LOND.

A CASE of surgical emphysema presenting features that seem worth recording recently came under my notice.

The patient, an Indian, was injured in a railway accident wherein a portion of a train fell over an embankment some 40 feet high, and was found lying with a heavy baulk of timber across his chest. The accident occurred about 9.30 P.M. I first saw him at about 12.30 A.M., when owing to the difficulty of the circumstances and the numbers of others injured, an exhaustive examination was not possible. He then showed enormous swelling of the face, neck, and trunk generally, the crepitus of surgical emphysema being everywhere obtainable. There being no obvious immediate treatment called for, I left him in order that I might attend to others whose injuries were more amenable to first aid, and I cannot say if the limbs were at that time involved.

He was next seen some six hours after, when the injured had been conveyed to hospital, and I noticed that while awaiting his turn to be carried into the hospital he was unconcernedly smoking a cigarette. He showed little respiratory distress and talked intelligently. By this time the emphysema involved the whole trunk, the neck, face, whole of the scalp, the arms as far as the wrists, and the legs to just below the knees. Pain was complained of on pressure over the lower ribs of the left side, though no actual fracture of ribs could be made out owing to the condition of the subcutaneous tissues. There was no external wound. Dr. Lucius Nichols, who kindly assisted me to deal with the injured, expressed his opinion that further entry of air into the tissues might be prevented if an attempt was made to close the entry to the pleuræ, but while preparations were being made to do this the patient suddenly exhibited most extreme dyspnœa and the pulse became impalpable, and he died in two or three minutes from the outset of these symptoms.

At the post-mortem examination the seventh rib on the left side was found to be fractured and a fragment of bone had penetrated the lung for a distance of one or one and a half inches. The lung showed no sign of collapse, nor was there any pneumothorax.

The points of interest exhibited by this case are, I think: (1) The great extent of the surgical emphysema; (2) the rapidity of its spread; and (3) the fact that death was seemingly due to sudden syncope rather than asphyxia, as evidenced by the comparative absence of dyspnœa until within a few moments of death.

Magadi Junction, British East Africa.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Operative Treatment of Tumours of the Cæcum and Colon.

A MEETING of this society was held on Oct. 26th, Sir J. BLAND-SUTTON, the President, being in the chair. A discussion was held on the Operative Treatment of Tumours of the Cæcum and Colon, especially in relation to immediate resection, colostomy combined with secondary resection, and short circuiting.

Mr. H. J. WARING opened the discussion from the point of view of malignant disease of the cæcum. He said that malignant disease of the cæcum in the majority of cases was a columnar-celled carcinoma, usually of the exuberant type, forming a mass protruding into the lumen of the cæcum, or less commonly an annular ring of new growth, scirrhous in character, and tending at a comparatively early stage to give rise to obstruction in the intestinal canal. Generally the exuberant type of growth commenced in the region of the ileocæcal valve, whilst the annular type was more common where the cæcum passed into the ascending colon. Occasionally, however, a constricting growth might be met with on the proximal side of the ileocæcal valve, in which case it would be found to commence in the mucous membrane of the most distal part of the ileum and to involve the cæcum by direct extension. A small proportion of neoplasms of the cæcum were sarcomata, and these usually commenced in the wall of the cæcum beyond the ileocæcal valve. He exhibited specimens of these different forms of growth. Included with the cæcum was, he supposed, the vermiform process. True carcinoma of this process in his experience was extremely rare. Some years ago he investigated 600 consecutive cases of disease of the vermiform process, and no single case was definitely shown to be true carcinoma. In the museum of St. Bartholomew's Hospital there were two specimens which had been called carcinoma. They, however, histologically presented more the characteristics of endotheliomata. They were removed from patients aged 27 and 29 respectively. The two specimens were exhibited, and in addition a microscopical preparation of a similar condition. When compared with carcinoma in other parts of the body, carcinoma of the cæcum (and other portions of the colon) was, on the whole, he thought, less malignant, the rate of growth of the neoplasm being slower, infection of lymph vessels and glands later, whilst visceral secondary growths only appeared when the affection had existed for a considerable period. This diminished malignancy was especially the case when the neoplasm was of the adeno-carcinomatous type and extended into the lumen of the bowel as a cauliflower-like protuberance. Sarcoma, on the contrary, appeared to be quite as malignant as when occurring in other parts. Concerning frequency he found that during the years 1909–13 107 cases of malignant disease of the large intestine (excluding the rectum) were admitted into the surgical wards of St. Bartholomew's Hospital, and of these 17 were examples of carcinoma of the cæcum. No case of sarcoma of the cæcum was met with during this period nor of carcinoma of the vermiform process. As regards treatment, cases of malignant disease of the cæcum could conveniently be considered under the following groups:—

1. *Cases in which the patient's general physical condition was good, there were no marked signs of intestinal toxæmia or anæmia denoting toxic poisoning from disintegration of the growth, absence of intestinal obstruction, whilst the tumour in the cæcal region was movable.*—This was the most favourable class of case, but unfortunately few patients presented themselves for treatment at this stage, or if they did, refused operative help. The operation which in his opinion was to be recommended was resection of the growth, together with the adjacent portions of the ileum and colon and also the lymph vessels and glands receiving vessels from the diseased area, followed by lateral anastomosis of the ileum and colon. When the anastomosis had been completed and the cut ends of the ileum and colon inverted, the two blind ends should be fixed to the parietal peritoneum of a portion of the external wound, so that if any leakage took place it might do so externally and not into the peritoneal cavity. A small drain should be passed down to the region of the fixed inverted ends for this purpose. If no leakage took place it could be removed after a few days, whilst if leakage did occur it would at once become manifest and a portion of the external wound could be opened up so as to facilitate the exit of any material which might pass from the intestine. Occasionally sloughing of a portion of the inverted ends occurred, in which case extension of a septic process to the peritoneum would be avoided. He had just received a letter from a hospital patient upon whom this operation had been done in 1910; he stated that he was still quite well, could walk eight miles a day, and do his work as a carpenter.

2. *Cases with acute intestinal obstruction, presenting signs of intestinal toxæmia, and with a mass in the right iliac fossa diagnosed as a diseased cæcum.*—When a patient had definite signs of intestinal obstruction and consequent intestinal toxæmia the plan of treatment which was most likely to be followed by a successful result was immediate enterostomy, and when the obstruction and toxæmia had been combated resection and anastomosis. The parietal incision should be made in the right iliac fossa and the portion of ileum above the cæcum fixed in the wound and drained. Often it would be found of considerable advantage in these cases to bring the cæcum, portions of colon and ileum and adjacent mesentery with contained lymph glands out through the external wound and to fix the mass there as a "protrusion," the ileum being drained as already mentioned. At the expiration of a few days the entire mass might be cut off, leaving two enterostomy openings. At a later date the spur between the two openings could be destroyed with an enterotribe, and the external opening closed. This method of treatment was most applicable in patients whose general physical condition was not good and in whom there was considerable doubt that they would survive a severe excision and anastomosis operation. In those cases in which a simple enterostomy was performed, after the patient had recovered from the intestinal toxæmia and the general condition had improved, a resection and lateral anastomosis in the manner already mentioned should be carried out.

3. *Cases in which the mass connected with the cæcum was attached either to the floor of the right iliac fossa or to the adjacent portion of the abdominal wall, on which account excision was considered inadvisable; and signs of acute intestinal obstruction were absent.*—In this group of cases in his opinion the best method of treatment was ileo-colostomy, the artificial communication or anastomosis being made between a coil of the ileum, a little above the ileocæcal valve, and the transverse colon, at its most dependent portion. This, of course, was a palliative operation, but often patients lived a considerable time in comparative comfort. He had notes of cases where life had been prolonged in this manner for 18 months and two years.

4. *Cases of acute intestinal obstruction due to malignant disease of the cæcum, but in which it was not possible to localise the site of the disease owing to abdominal distension.*—A median exploratory incision should be made in these cases, and the further treatment determined according to the pathological conditions discovered. Usually it was safest to perform first an enterostomy and establish drainage. When the patient had recovered from the toxæmia due to the obstruction and the general condition had improved, the further treatment could be carried out. Thus, if the cæcal tumour was found to be operable, resection and lateral anastomosis could be performed, and at a later date the enterostomy opening closed, whilst in inoperable cases ileo-colostomy should be done, the enterostomy opening being made use of in establishing the communication with the transverse colon.

It occasionally happened that a diagnosis of carcinoma of the cæcum was made, and on operation the pathological condition was found to be either actinomycosis or tuberculosis in the ileocæcal region. He showed a specimen obtained from a patient in whom he had made the diagnosis of carcinoma of the cæcum and on exposure of the hard mass in the right iliac fossa found it to be actinomycosis. The patient was treated by large doses of potassium iodide, and at the end of 12 weeks had apparently recovered. Eight years afterwards the patient again came under his observation and then had an extensive inoperable carcinoma of the stomach from which he died. Post mortem, nearly all traces of the extensive mass in the right iliac fossa had disappeared, the only remains being a few adhesions and obliteration of the proximal portion of the vermiform process.

Mr. JAMES SHERREN said that the divisions of the large intestine with which he had to deal had received various names. These until recent years depended upon its relations to the pelvis—the descending colon being that part outside the limits of the false pelvis, the sigmoid that attached to the wall of the false pelvis, and the rectum that below the level of the pelvic brim. The descending colon still terminated at the iliac crest, but the sigmoid had been anatomically separated into two, one part—the iliac colon—being attached to the iliac fossa without a mesentery, the other—the pelvic colon—forming a loop completely surrounded by peritoneum and attached by its mesentery to the side wall of the pelvis. Its lower limit had been altered, and it now terminated where the complete peritoneal investment of the gut ceased—usually about the third piece of the sacrum. Anatomical divisions were often unsuited for surgical purposes. As an example, he indicated the duodenum with its three or in some classifications four anatomical portions, best divided for surgical purposes into two parts, supra- and infra-ampullary. For the purposes of surgery the iliac should be included with the descending colon, for both portions were as a rule bare of peritoneum posteriorly, features which had an important bearing on operative procedures. He would therefore divide his remarks into (1) the treatment of tumours of the pelvic colon, and (2) of those of the descending, including the iliac, colon. The pelvic colon was the most common site in the large intestine for the development of carcinoma, the descending colon the rarest. Thus among 376 cases of carcinoma of the colon treated at the London Hospital during the ten years 1901–11, 211 were of the pelvic colon, 20 of the descending colon. Among 68 cases which had been under his care, in 36 the growth was situated in the pelvic colon, in five in the descending colon. The problem of the surgical treatment was complicated on account of the rarity with which the diagnosis was made before the onset of urgent symptoms of intestinal obstruction. Attacks of pain, diffuse, or in some cases localised in the right iliac fossa and leading to the diagnosis of chronic appendicitis, were, however, very rarely absent. In one of the cases in which he operated for acute obstruction the appendix had been removed a few weeks previously on account of pain in the right iliac fossa thought to be of appendicular origin. Among the London Hospital cases over 40 per cent. were operated on for acute obstruction. In 24 of his own cases the operation had to be carried out for the relief of obstruction. In the cases with urgent obstruction free drainage of the distended intestine was indicated. At the same time, if the condition of the patient admitted, a careful examination should be made of the growth, glands, surrounding peritoneum, and liver to decide the question of attempting excision at a later date. Primary resection should *never* be carried out in the face of urgent obstruction. If in any doubt it was wiser to drain temporarily before attempting a resection. The seat of drainage and its relation to the operability of the tumour must be considered. In the discussion on malignant disease of the large intestine at the International Medical Congress of last year Bastianelli and others were strongly in favour of a preliminary cæcostomy.[1]

---

[1] THE LANCET, August 16th, 1913, p. 480.

Unless compelled by disaster to the cæcum, present or impending rupture or gangrene, he considered it an unwise procedure. It necessitated, in cases suitable for removal, a three-stage operation. In the inoperable cases the discomfort of an artificial anus in the cæcal region was undoubtedly greater than that of one in the transverse colon or left iliac regions. Among his series cæcostomy was necessary in three; in only one was he able to do an excision followed in 14 days by closure of the cæcostomy. Operation in which the growth was exteriorised and removed at the original operation (Paul), or after an interval (Mikulicz), leaving the closure of limbs to a later stage, he did not favour. It was applicable only for growths in a movable pelvic colon, and even here removal of sufficient bowel with its lymphatic supply was difficult, if not impossible. Closure of the artificial anus was tedious and might require several efforts. In cases of intestinal obstruction in which carcinoma of the sigmoid was diagnosed or suspected as the cause he opened the abdomen by an incision through the middle of the lower part of the left rectus muscle. After establishing the presence of a growth and its operability, the condition of the intestine above, and especially the cæcum, was investigated. If the condition of the latter was good he made an artificial anus a few inches above the growth. If operable he excised it ten days or a fortnight later, together with the carcinoma and its lymphatic area, and re-established the continuity of the intestine. If care were taken to have the bowel well emptied and the skin cleansed in the "old-fashioned" way and compressed with 1 in 20 carbolic for half an hour before operation the risk of infection was slight. With large intestine completely covered by peritoneum, end-to-end anastomosis by suture had proved perfectly satisfactory in his hands. It was wise, however, to pass a tube down to its site for a few days, as with the most careful suturing, and even in the absence of any tension, some temporary leakage might ensue. When the growth was involving the upper part of the pelvic colon the anastomosis might have to be made to the iliac colon, and in this case and every case in which the peritoneal covering of the gut was incomplete, lateral anastomosis should be the method adopted. When the carcinoma affected the lowest part of the pelvic colon, anastomosis by invagination, as described by Lockhart Mummery in 1908 and by Balfour from Mayo's clinic in 1910 was the most satisfactory procedure. He had carried out two-stage operations on these lines in 8 cases with 1 death. This was due to acute intestinal obstruction, the result of a coil of small intestine becoming adherent to a bare area of peritoneum on the outer side of the anastomosis. This acted as a band under which another coil became strangulated. The patient was at that time apparently well, three weeks after the operation. In the first two cases of acute intestinal obstruction due to carcinoma of the pelvic colon that came under his care he carried out primary excision; both died. He had not used this method since. The after-history of the 7 survivors was as follows: 1 was alive and well 4½ years after operation; 1 died from recurrence in 4 years, after being in perfect health for 3½ years; 1 died from recurrence in 28 months, after 2 years of health; 1 after 2 years of health showed signs of recurrence; 1 died from recurrence in 19 months, remaining well for 15 months; 1 from recurrence at 9 months; and 1 from recurrence at 7 months. Inguinal colostomy in inoperable cases rendered life more tolerable. In some cases the quality of life remaining was good, and was certainly prolonged in comfort. Colostomy was carried out in 20 cases of carcinoma of the pelvic colon, the left iliac operation in all except two. The remainder were complicated by general diffusion or abscess, rendering any operative relief impossible. Six died within a few days of the operation. He had been able to trace the following: 1 alive and well 6 years after; others at 12, 10, 5 months; the remainder died—1 at 2 years, 1 at 12 months, 2 at 10, 2 at 9, and another at 4 months after operation. He had operated upon 5 cases of carcinoma of the descending colon, in only one of which was acute obstruction present. The operation to be carried out in the presence of obstruction, the result of growth in this situation, would depend on the condition of the intestine above. Where this was obviously acute, transverse colostomy should be carried out. This necessitated a three-stage operation in the event of the tumour being removable. In cases of chronic obstruction lateral anastomosis of the transverse colon to colon well below the growth was the wiser course. This he carried out in two cases in which the tumour was too far advanced for excision. One was alive and apparently well nearly three years afterwards, the other lived for three months. In two cases six and two months ago he successfully carried out primary resection, restoring continuity by lateral anastomosis. His present practice in the treatment of carcinoma of the pelvic and descending colon might be summed up shortly: in all cases of acute obstruction, no matter if the tumour be easily removable, colostomy should be carried out—left iliac if the growth be in the pelvic colon, transverse if in the descending colon. In resection the lymphatic area draining the affected gut should be removed, continuity established by end-to-end suture if the gut had a complete peritoneal covering, by lateral anastomosis if incomplete, sufficient room being obtained by mobilisation.

Mr. E. M. **CORNER**, speaking of tumours of the transverse colon, said that no surgeon had an extensive experience of them on account of their relative infrequency, and because in the great majority of instances the surgeon was operating to relieve intestinal obstruction primarily, and found the carcinoma secondarily. Their relative importance was shown in the figures of the incidence of carcinomata in different parts of the abdominal colon—i.e., exclusive of the rectum. The figures had been gleaned from the records of St. Thomas's Hospital as contained in the St. Thomas's Hospital Reports for 1900–1911 inclusive: Carcinoma of the cæcum, 20 per cent.; carcinoma of the ascending colon, 10 per cent.; carcinoma of the hepatic flexure of the colon, 4 per cent.; carcinoma of the transverse colon, 18 per cent.; carcinoma of the splenic flexure of the colon, 2 per cent.; carcinoma of the descending colon, 6 per cent.; and carcinoma of iliac and pelvic colon, 40 per cent. Carcinomata of the colon were most frequent in the iliac and pelvic colon, then in the cæcum, and then in the transverse colon. In all other situations they were relatively infrequent. Carcinoma was more frequent where the "foodstuffs" remained and paused in their passage through the intestine than where they were in motion. Its incidence was more common in the colon on the right (hepatic) side than in the colon on the left—i.e., more common where the bowel contents travelled against gravity, and therefore more slowly than where they moved assisted by gravity. Of these carcinomata some remained quiet and produced no symptoms or signs until they were very far advanced. Others caused intestinal obstruction quite early in their course. In consequence, carcinomata in the various regions of the alimentary canal possessed various relationships to the clinical symptoms which might arise, such as acute intestinal obstruction. In other words, carcinomata in the different regions of the colon showed different pathological and clinical characters. In his most interesting address at Aberdeen their President, Sir John Bland-Sutton, said that surgeons tended to be of two kinds—technicians or craftsmen who improve the art of their profession, and biologists who improve the science of their profession.[2] It might be added that the value of the work of both had to be brought before and estimated by the clinicians. Hence he would suggest that the greatest and most important group of surgeons was the clinical, as they had to appraise the work of all other departments. To appraise the value of the pathological knowledge of the incidence of carcinomata of the large intestine obtained, as above, from the pathologist, an inquiry was made as to their relative importance in causing acute intestinal obstruction. The incidence of obstruction was as follows: Carcinomata of the cæcum, 4·1 per cent.; carcinomata of the ascending colon, 0·7 per cent.; carcinomata of the hepatic flexure of the colon, 2·5 per cent.; carcinomata of the transverse colon, 13·4 per cent.; carcinomata of the splenic flexure of the colon, 17·4 per cent.; carcinomata of the descending colon, 5·1 per cent.; and carcinomata of the iliac and pelvic colon, 59·8 per cent. These figures showed that: 1. Carcinomata of the cæcum, and still more carcinomata of the ascending colon, did not seem to obstruct the intestinal flow. The growths tended to be lateral and local in the gut wall, like carcinomata of the rectum; hence they did not obstruct the flow within the bowel as did a ring growth. 2. Carcinomata of the iliac and pelvic colon, splenic flexure, and transverse colon were quite different in their clinical behaviour, causing intestinal

---

[2] THE LANCET, August 1st, 1914, p. 293.

obstruction early in their course. 3. Carcinomata of the splenic flexure were infrequent, but practically always caused intestinal obstruction. Carcinomata of the hepatic flexure showed the same feature to a much less marked degree. Since many regarded the whole of the large intestine as an anatomical unity it might be as well to include amongst the carcinomata those of the rectum in the statistics showing the relative importance of the carcinomata of the large intestine in causing acute intestinal obstruction. Including these the figures were: Carcinoma of the cæcum, 3·3 per cent.; carcinoma of the ascending colon, 0·2 per cent.; carcinoma of the hepatic flexure of the colon, 1·7 per cent.; carcinoma of the transverse colon, 11 per cent.; carcinoma of the splenic flexure of the colon, 14·3 per cent.; carcinoma of the descending colon, 4 per cent.; carcinoma of the iliac and pelvic colon, 47 per cent.; and carcinoma of the rectum, 18·5 per cent. It would be seen that the asymmetrical and "lumpy," as contrasted with the symmetrical and annular, carcinomata of the right-sided segment of the colon were the least liable to cause acute intestinal obstruction. This clinical condition increased in frequency when the growth was in the transverse colon, at the splenic flexure, to reach its maximum clinical incidence in the iliac and pelvic colon, where it took the form of a ring-like band (from the disposition of the lymphatics) constricting the bowel. In the rectum, again, the growth was "lumpy" and asymmetrical in its disposition. It would be seen that, looked at from all points of view, carcinomata of the transverse colon occupied both pathologically and, to a less degree, clinically an intermediate position between cæcal and sigmoid carcinomata; whilst in cases of acute intestinal obstruction where the situation of the cause could not be ascertained, the preponderance of the left-sided causes over those on the right side suggested the very practical point of opening the abdomen through the left rectus muscle. Clinically carcinomata of the transverse colon exhibit these characteristics: the absence of warning to the patient, the unannounced onset of acute intestinal obstruction, and the presence of a small annular growth. Hence, when it came to treatment the surgeon had two things to attend to—intestinal obstruction primarily and a carcinoma of the transverse colon secondarily. The former was a condition in which myriads of micro-organisms abounded. The organisms were responsible for many and much of surgical failures in the removal of growths from the colon. Hence he would urge that the surgeon was very unsound who attempted to do constructive work—e.g., the plastic work of an anastomosis in the face of this sepsis. Therefore, when any degree of acute intestinal obstruction was present, a temporary colostomy alone should be done. The artificial anus and the growth should be removed about a fortnight or three weeks later, the ends of the resected bowel sutured and closed, and the cæcum anastomosed to the sigmoid. It was noteworthy that it was strongly advised that the surgeon should do nothing, not even the removal of the growth, but relieve the intestinal obstruction. In the speaker's experience patients so treated did better in both their early and late clinical post-operative stages than if the growth was removed and Paul's tubes inserted. It was far better to leave the reaction of the growth until the time of the anastomosis. An inflamed growth was far more likely to lead to trouble if any attempt was made to remove it than was an uninflamed growth. This remark applied both to near and remote consequences. Thus he did not like "playing" with inflamed growths any more than he liked "playing with fire." The best work was usually done with cool materials. From time to time carcinomata of the transverse colon were large, and their removal might require a partial resection of the stomach, or they might become adherent to the umbilicus and discharge through it. But these features were unusual, and need not be introduced into a discussion on general principles. In practical surgical work they were far most likely to be called upon to relieve the intestinal obstruction caused by a carcinoma of the colon. Having done this it might have to be decided how to resect this carcinoma. The anastomosis might be made local to the excised carcinoma when possible, and there might be an oblique or circular enterorrhaphy. If, as was the usual case, the excision of the artificial anus and the growth left too little transverse colon behind to allow of an end-to-end anastomosis being done he believed the best proceeding was to close the ends of the bowel, cut off the caput coli with the appendix, and anastomose by implanting the cæcum into the upper rectum or sigmoid. This anastomosis had the advantages of keeping the "second stomach"—the cæcum and ascending colon, so that less food escaped absorption than if these structures were removed; the appendix, always abnormal in these cases, was removed, and the anastomosis, though made far from the growth, was yet conservative. With regard to proceeding to radical measures in the excision of the growth his advice would be: "Never try radical measures on an inflamed growth when they can be avoided. Do not be deterred by the presence of enlarged glands as many are inflammatory, but beware of intraperitoneal adhesions." In other words, the surgeon need not be put off by extraperitoneal inflammation, but he should be easily stayed by intraperitoneal inflammation. There was no doubt about the attempt at the spontaneous cure of the carcinoma by the production of contracting scar tissue by the inflammation of the contiguous structures. It was the contraction of this non-carcinomatous tissue which produced the intestinal obstruction in ring carcinomata—not the carcinoma as in the cæcum and rectum. Hence ring-carcinomata were more amenable to operation and gave better results from operation than did local and lumpy carcinomata. Hence he would make the statement that the results from the judicious resection of the ring carcinomata of the transverse, iliac, and pelvic colon gave better results than did resections for asymmetrical carcinomata of the cæcum and rectum. To demonstrate this it was practically always necessary to do the operation in two stages, and patients did not always like this procedure. Firstly, one should do a colostomy, relieve any obstruction, and make the tissues less septic; secondly, resect the growth, anastomose, and close the colostomy. In conclusion, he must say that he regarded a transverse colostomy as only a temporary measure. Colostomies had in general to be where the disposition of troubles put them. Inguinal colostomy was the form for choice. In general its results were better, more certain, and its performance easier, and it left a longer piece of colon for absorption. Colostomies were often olfactorily unpleasant, and something must be left to the choice of the patient. The transverse colostomy was apt to be more obtrusive. Mr. Corner said he had now in hospital a poor woman with a transverse colostomy who had a large prolapse of the mucous membrane from the bowel between the colostomy and the spleen; an ascending prolapse—a condition unknown in inguinal colostomy. And it was a matter of taste whether the patient preferred to have fæces in his umbilicus or in his pubic hairs. But putting aside all æsthetic considerations, on surgical grounds he thought the inguinal form of colostomy the better. A transverse colostomy had a secondary and distinct rôle in surgery.

Mr. H. W. **Carson** said that the following was a summary of his last 20 cases of tumour of the colon: 1 case of actinomycosis of the cæcum, 1 case of ileocæcal tuberculosis, 4 cases of growth of ascending colon (malignant , 1 case of growth of splenic flexure (malignant), 3 cases of growth of descending colon (1 innocent, 2 malignant), and 10 cases of growth of sigmoid flexure (pelvic colon). He had brought two specimens of growths of the ascending colon for which he had done extensive resections, and their microscopical slides, which were interesting owing to their diverse characters. Both occupied practically the same site—i.e., within an inch of the ileocæcal valve; both were large growths with ulcerated nodular surfaces; both were malignant, but one was a spheroidal-celled medullary carcinoma and the other was a typical columnar-celled carcinoma. Of the two he believed it was agreed that the former was the more rapidly growing and had a worse prognosis. Clinically, these growths were quite different in their course from growths of the colon at and below the splenic flexure. They formed large masses, giving rise to tumours which were nearly always palpable and sometimes visible; there was a comparatively long history of intestinal discomfort—e.g., pain, diarrhœa, blood in the stools—and they rarely gave rise to obstruction. Comparing this with the history of growths of the left colon, of the 13 malignant cases in his list 6 had acute obstruction as the first sign, 3 had acute obstruction following a history of intestinal discomfort, 1 had chronic obstruction, and only 3 were free from obstruction when they came under his notice. None had diarrhœa or blood in the stools, 4 had

had pain and 5 had had long-standing constipation. It was this risk of obstruction which led to the heavy death-rate, for he found that of the 9 cases where acute obstruction had occurred 6 died shortly after operation. He had no doubt that many cases in whom obstruction seemed to be the first sign had had premonitory symptoms such as abdominal pain, irregularity of the bowels, or flatulent distension, and there was much to be done to educate the public to the necessity for seeking advice when these symptoms occurred in late middle life. With regard to treatment he said that it was generally agreed that in acute obstruction no attempt should be made immediately to restore the continuity of the bowel. The methods of relieving the obstruction varied between a cæcostomy, a colostomy (transverse or descending), and the excision of the growth with the formation of an artificial anus. Of these methods he was in favour of the last if the growth was found to be free of adhesions. If there was any difficulty in delivering the growth through the wound he preferred a colostomy in the neighbourhood of the growth rather than at a distance, as this prevented stasis in the intestine between the opening and the growth which might keep up the toxæmia. The subsequent operation of excision should be done at the earliest in three weeks. He was not satisfied that even if there was no absolute obstruction it was safe to do an immediate anastomosis of colon to colon. In the ascending colon the conditions were absolutely different. Obstruction was rare and anastomosis was made between the ileum, which was rarely injured, and a healthy portion of colon well beyond the disease. It remained to decide upon the best course to adopt. If the growth was inoperable a short-circuiting operation should be done. If the growth was operable it should be removed, and the important point to settle was the necessity of removing the glands which might be most implicated at the highest point—namely, near the origin of the ileo-colic artery from the superior mesenteric. It was probably best to start the operation at this point, tying the ileo-colic artery near its origin after dividing the transverse colon at the selected spot, and removing the whole chain of glands as they lay on the ileo-colic and right colic vessels. The ileum should be divided at least six inches from the ileo-cæcal valve and a lateral anastomosis done between the ileum and the transverse colon after closing both ends. The re-peritonisation of the raw surface left after the removal of the ascending colon was very important.

Mr. G. E. Gask raised the question as to what should be done in cases of acute obstruction. He put in a plea for short-circuiting rather than colostomy. It was more pleasant and if a further operation was advisable an anastomosis had already been obtained. The mortality of the conditions under discussion was very high, and this was due, he thought, to sepsis, already present in the bowel. The peritonitis following operation was due to infection on opening the bowel. No satisfactory operation had been devised by which a bowel could be opened which was free from danger by sepsis. He favoured lateral anastomosis rather than the end-to-end method, after excision of the growth.

Mr. F. Swinford Edwards agreed that growths of the large intestine were not highly malignant. He used end-to-end anastomosis and always left in a drainage tube for a few days. After excision of malignant growth in the pelvic colon there was considerable danger of stenosis. This he treated by a large Kelly's tube. He had found the sigmoidoscope of great value in the diagnosis of growths in the pelvic colon. He had abandoned inguinal colostomy in favour of hypogastric colostomy through the rectus.

Dr. Herbert French spoke of the difficulty of diagnosis and of the possibility of obtaining aid from bismuth meals or enemata, from sigmoidoscopy, and from chemical examination of the fæces for occult blood or other bodies. Was wasting in a patient with suggestive symptoms a clear indication of the need for operation?

The President also agreed that such growths were often very slow in growth. He had seen more than one case where a secondary growth in bone had been operated upon on the supposition that it was primary. By microscopical examination it had proved to consist of columnar cells and secondary to growth in the bowel. Only after watching the patient for some months did symptoms arise pointing to the original lesion. This showed how insidious such growths were. He had also followed up cases five, seven, and nine years after colostomy had been done, and the growth had been shown to be carcinomatous microscopically. It was sometimes difficult even at the operation to be sure that malignant growth was present and to distinguish it from conditions which resembled it, like hyperplastic tuberculosis and actinomycosis. There was, therefore, plenty of excuse for the medical attendant who had not this help. If he performed a transverse colostomy he always removed the navel at the same time.

Mr. Corner, Mr. Sherren, and Mr. Waring replied.

Bradford Medico-Chirurgical Society.—The opening meeting of this society was held on Oct. 20th. Dr. A. Manknell delivered the presidential address on Vaccination. After thanking the members of the society for electing him to the chair, Dr. Manknell said he hoped to refresh their memories on the subject of vaccination. Jenner's wonderful discovery had had far-reaching effects in its influence on the course of science and in the development of vaccine treatment, which had so largely bulked in their minds during the last ten years. After tracing the history of small-pox from the earliest times, Dr. Manknell then went on to show by means of statistics how it became apparent that revaccination was necessary. The pathology of small-pox was then discussed in detail, and statistics were given showing the influence of vaccination upon the severity of the attacks, the modification of the disease, and the alteration of the age-incidence. As regards the last, before vaccination small-pox was a disease of infancy. Vaccination had raised the age-incidence in two ways: 1. By reducing the number of persons in any given population who are susceptible to small-pox it reduces the chances of epidemics and lengthens the interval between them. 2. By rendering those once vaccinated insusceptible to small-pox for a period of years it raises the age-incidence in such to a higher range than among the unvaccinated. The influence of vaccination upon the fatality of small-pox was also shown in a marked degree by numerous figures, and Dr. Manknell laid particular stress on the fact that insufficient vaccination is a great evil, statistics showing that in patients with only one scar the ravage of the disease is infinitely more severe than in those patients with three or four scars. As instancing the value of revaccination, Dr. Manknell quoted the continental armies and gave striking figures. The influence of sanitation on small-pox was then discussed in full.—The meeting closed with a vote of thanks to the President for his address.

Ulster Medical Society.—The opening meeting of this society was held in the Medical Institute, Belfast, on Oct. 29th. The retiring President, Mr. A. B. Mitchell, having, in a valedictory address, thanked the Fellows and Members, and especially the honorary secretary, Mr. S. T. Irwin, for the help and support they had extended to him during the past session, in very suitable terms, introduced his successor, Dr. J. S. Morrow, who gave an introductory address on Disease in its Medico-Legal Relation to Accident. From his extensive practical experience as medico-legal adviser to the great shipbuilding yard of Harland and Wolff and other shipbuilding companies and insurance societies, Dr. Morrow was able to bring forward unique examples of cases in which disease existing before or occurring after an accident led to litigation requiring the most careful diagnosis and medico-legal management. It is to be hoped such a useful discussion of some of the most difficult medico-legal questions will be published in full. On the motion of Sir John Byers, seconded by Professor T. Sinclair, a vote of thanks was accorded to Dr. Morrow and to Mr. Mitchell. Copies of the Transactions of the Ulster Medical Society for session 1913–14, which constitute a large volume, were distributed at the meeting. It has been decided that in the present troubled times the annual dinner of the society is to be postponed.

West London Medico-Chirurgical Society.—A clinical meeting of this society will be held to-day, Friday, Nov. 6th, in the society's rooms, West London Hospital, Hammersmith, W. Cases will be shown at 8 p.m., and the chair will be taken at 9 o'clock.

Reviews and Notices of Books.

A System of Clinical Medicine dealing with the Diagnosis, Prognosis, and Treatment of Disease, for Students and Practitioners.

By THOMAS DIXON SAVILL, M.D. Lond. Fourth edition. London: Edward Arnold. 1914. Pp. xxviii. + 948. With 4 coloured plates and 120 figures. Price 25*s.* net.

THE fourth edition of the late Dr. Savill's well-known text-book of medicine has been thoroughly revised and brought up to date by his widow, with the assistance of various experts in several of its departments. Dr. Savill's original object in writing the book was the production of a volume in which medicine should be considered from the point of view of symptomatology. As he pointed out, practical experience shows that patients seek medical advice because they have some morbid symptom to complain of; accordingly he began his descriptions of the various diseases by an account of the symptoms to which they give rise. Next, he devoted great attention to the diagnosis, so that the book might serve the purposes of a clinical index of diseases, and he laid great stress on the clinical advantages of the habit of passing in rapid review all the possible diseases that might account for a patient's leading symptom.

It is needless to say that Dr. Savill's plan of campaign is one of the greatest difficulty, as compared with the method of regarding diseases as separate entities which has almost invariably been adopted by the writers of medical text-books. Yet there can be no doubt that he executed his plan with great skill and attained a large measure of success, neglecting nothing in the way of etiology, pathology, and treatment to make his work complete. Important diseases are indicated by the use of large type, rarities are described in smaller type, and abundant cross references are given to avoid repetition and increase the utility of the book.

The editor's work has been done with skill and thoroughness; there is an excellent index. The volume contains an immense amount of information, and may be warmly recommended to senior students and practitioners of medicine on the look out for a sound summary of clinical diagnosis.

Gunshot Injuries: How they are Inflicted, their Complications and Treatment.

By Colonel LOUIS A. LAGARDE, United States Army Medical Corps (retired). London: John Bale, Sons, and Danielsson, Limited. 1914. Pp. 398. Price 18*s.* net.

THE writer of this treatise speaks with authority on the subject, having lately been commandant and professor of military surgery in the United States Army Medical School, as well as professor of the same subject in the University of New York. The results of the experience of army surgeons in the Spanish-American, Boer, Russo-Japanese, and Balkan wars have been compared with those in pre-antiseptic times, the characteristic features of the injuries produced by modern high velocity projectiles from small calibre rifles being dealt with in careful detail. The first five chapters treat of gunshot wounds in general, their characteristic lesions, symptoms and treatment. The next seven deal more particularly with injuries of the head, spine, chest, abdomen, blood-vessels, joints, and long bones seriatim. The medico-legal aspect of such wounds, and the application of X ray apparatus in the field are considered briefly in conclusion.

The rifle in use at the present time by the United States Army weighs 9½ lb. and measures 24 inches in the barrel. The bullet (modified in 1906) weighs 150 grains, and is 1·08 inch long; the powder charge is 48 grains. The striking energy of the bullet is 2400 foot pounds, the muzzle velocity 2700 feet per second, and the extreme range of the rifle 4891 yards. It is sighted for 2850 yards. With this rifle used as a single loader 23 aimed shots have been fired in one minute; using magazine fire 40 shots in a minute have been fired from the hip without aim. The 1906 model bullet now in use has a length of 1·095 inch, and a maximum diameter of 0·3085 inch, weighing 150 grains; it is of lead, with 3·3 per cent. of tin, enclosed in a cupro-nickel jacket. It is claimed that the present weapon is the most accurate rifle in the world. "With a high muzzle velocity and a flat trajectory little remains to be desired, unless the trajectory can be further lowered, and the continuous danger space for a height of 68 inches extended from the present range of 730 yards to a range of 1000 yards."

With regard to the observations and experiments made as to the effects of bullet wounds on cadavers, Colonel Lagarde goes into considerable detail. He believes that the experimental procedure of firing into cadavers, animals, and inanimate matter is the best way to ascertain the effects of projectiles on tissues, at any rate in peace. As to shell wounds, it is mentioned that one of the chief menaces in naval warfare to-day will be poisoning from powder gases arising from bursting shells. Surgeon-General Stokes has described two types, one resembling gas poisoning, the other irritative in its effects.

The extreme importance of infection in gunshot wounds is dealt with in the fourth chapter. After referring to the experiences of the great Civil War, and Weir's admission that the surgeons were more fatal to those under their care than the battle—"death followed the path of the surgeon, with his poisonous technique and dressings"—the author shows the regular decrease that has occurred in mortality from wounds in successive campaigns, the figures referring to the cases that "reached the hospital." In the Civil War the mortality was 14·3 per cent., in the Spanish-American war 6·0, in the Boer war 8·0, in the Russo-Japanese war 5·8 (Japanese) and 3·4 (Russian). "Antisepsis and the use of projectiles of the reduced calibre rifle have combined to bring about marked beneficence in the war wounds of modern times." To take gunshot injury of the knee-joint as an example: in the Civil War the mortality from this injury was 53·7 per cent., and of the rest none returned fit for duty, as all who recovered had suffered amputation. With antiseptic treatment in the Russo-Turkish war, 1877–78, the mortality was 11·1 per cent., but no cases returned fit for duty; in the period 1898–1902, the United States Army statistics (76 cases) gave a mortality of only 6·5 per cent., and 39·4 per cent. returned fit for duty; finally, in the Santiago campaign of 1898, the injuries resulting from small calibre missiles, of 17 cases the whole recovered, and 81 per cent. returned fit for duty. This excellent result was due partly to the humane features of the reduced calibre bullet, partly to the use of antisepsis. The various theories that have been suggested to account for the so-called explosive effects of modern projectiles are considered. High velocity is the most potent factor, and the true cause of these explosive effects is "the transfer of energy from the bullet to particles of its own composition when it disintegrates, as well as to spiculæ of bone, or particles of fluid, or soft tissues." The treatment of the various kinds of wounds from gunshot is discussed fully according to the regions affected.

The illustrations are numerous and excellent, and the directions are clear and precise. The manual is to be thoroughly recommended.

The Story of Bethlehem Hospital from its Foundation in 1247.

By EDWARD GEOFFREY O'DONOGHUE. London: T. Fisher Unwin. 1914. Pp. 427. Price 15*s.* net.

FOR upwards of 650 years the Hospital of St. Mary of Bethlehem has, in the words of the founder's deed poll, ministered to "the benefit in manifold ways of the City of London," and since 1377 more particularly by caring for those stricken in mind. Ever since the year 330 there had existed at Bethlehem the Church of the Nativity, built and dedicated by Constantine, and in the year 1247 Simon FitzMary, an alderman of London, gave all his lands in the parish of St. Botolph without Bishopsgate for the foundation of a priory with a prior, canons, brothers, and sisters, which priory was to be a daughter house of the mother church at Bethlehem, was to receive the Bishop of Bethlehem and the other clergy of that house whensoever they should come, and besides this duty should celebrate divine services for the souls of sundry persons mentioned by the founder, and in addition for all the souls of the faithful departed. The rule followed was that of the Augustinians.

The priory apparently met with misfortune, for in 1346 the master and brethren petitioned that it might be received under the protection and patronage of the City. They had, says the petition, suffered from "losses, damage to property, acts of violence, oppression, extortion, and danger of death; from reviling, scandal, and their own dissensions." On Oct. 15th the City took the house and order under its protection, and the institution seems to have enjoyed quiet until 1375, when Edward III. seized it as an alien priory. What happened then is uncertain, but in 1377 certain lunatic patients were removed from "The Stone House" at Charing Cross to the Hospital of St. Mary of Bethlehem, so evidently the hospital was able to continue some at least of its work.

Between 1388 and 1403 the hospital had a porter, one Peter Taverner, who was also the treasurer, and who seems to have been a knave of the first water. In 1403 the hospital also had under care six male lunatics, with material for their safe keeping—to wit, 4 pair of manacles, 11 chains of iron, 6 locks and keys, and 2 pair of stocks. The graceless Peter, besides diverting the subscriptions of the charitable to his own use, was charged with stealing a number of blankets, sheets, and mattresses, and in addition the aforesaid chains, manacles, and locks. He was eventually fined £100, which he does not seem to have paid, and was also removed from his post. The hospital continued to run the not unusual career of scandals, commissions of inquiry, reformation, further scandals, more commissions. In 1457 John Arundell, chaplain and physician to Henry VI., was appointed Master, and about 70 years later—namely, in 1529—a man of a very different stamp, George Boleyn, obtained the post. At the great spoliation Bethlehem, together with St. Bartholomew's Hospital, was grudgingly granted to the City. In 1619 another physician was elected Keeper or Master, Hilkiah Crooke, a not very reputable personage, who was eventually dismissed his post and called upon by the College of Physicians to resign his Fellowship.

The Great Fire spared the hospital, but by 1674 the buildings had become so ruinous that it was decided to remove and rebuild it on another site. This site was in Moorfields, and the architect chosen was Robert Hooke, best known as a natural philosopher. But he was also a great architect, as his building for the second Bethlehem Hospital shows. The main building was finished in 1676. This is the "Bedlam" which figures so prominently in seventeenth and eighteenth century literature and in Hogarth's pictures, and one of the most remarkable figures of the hospital during this stage of its career was Dr. Edward Tyson, physician from 1684 to 1708. He was one of the earliest to institute a system of "after-care," but even his efforts could not prevent the disgraceful scenes in Bedlam on public holidays when the unfortunate inmates were made a show and a mockery; and it was not until 1770 that it was ordered that admittance should be by ticket only, and that accredited visitors should be accompanied by keepers or nurses. By 1800 Hooke's beautiful building, owing to insecure foundations and the tampering with the brick piers of the basement for purposes of increased storage, was in a very alarming condition, and it was decided to rebuild the hospital elsewhere. A site was chosen in St. George's Fields, and the new buildings were begun in 1812 and opened for patients in 1815. The architect appears to have been E. John Gandy, though his plans were altered by James Lewis, the surveyor. At this date the treatment of insanity began to be studied in a more gentle and reasonable spirit, owing in great measure to the interest aroused in the subject by the insanity of George III. Tuke in England and Pinel in France had been for some time experimenting in treatment without coercion. In 1837 the Charity Commissioners inspected Bethlehem, and on June 28th, 1851, the Commissioners in Lunacy made the first of their periodical inspections. That year, too, Dr. W. C. Hood was elected resident physician and lit the light of progress which has ever burned more brightly; not only metaphorically did he throw light on dark places but literally, for it was he who did away with the heavy iron gratings to the windows.

So we leave Mr. O'Donoghue's most interesting record of an institution which has endured for nearly seven centuries. The arms of the hospital show in a way an epitome of its history, and in all points save one they are those originally designed; there we see the basket of bread in allusion to Bethlehem, "The House of Bread," and again the star. The third charge used to be a chalice with the Host issuing from it. By the middle of the seventeenth century the arms had apparently been forgotten, for the governors asked Sir William Dugdale on the point. He it was who provided them with the old arms except that a skull replaces the Host in the chalice, a curious alteration upon the meaning of which it is legitimate to speculate. Dugdale was no bitter Protestant, so the substitution cannot be a deliberate insult levelled at the chief rite of Christianity. Did he wish to emphasise the fact so prominent in the history of spiritual conflicts that the attack of the powers of evil is most violent at the time of spiritual exaltation? Or, for Dugdale was an ardent antiquarian, was he thinking of the Pagan version of the Grail legend as found in the Mabinogion when Peredur was in the castle of the lame king and saw two maidens enter, "which had between them a large salver in which was a man's head, surrounded by a profusion of blood"? But whatever be the meaning of the change, Bethlehem Hospital is now in very truth a place where those troubled in mind receive the gentlest and most careful treatment.

Diagnostics of the Fundus Oculi.

By EDWARD L. OATMAN, M.D., Surgeon, Manhattan Eye, Ear, and Throat Hospital, &c. Comprising one volume of text, with 234 illustrations and 4 coloured plates, and two portfolios containing 79 stereograms and 8 diagnostic cards. Troy, New York: The Southworth Company. Pp. 303.

Dr. Oatman has attempted in these volumes a greater task than the title indicates. It is nothing less than an endeavour to write a treatise of ophthalmology on the basis of individual cases. Such a herculean task is foredoomed to failure, but it has been a brave fight against odds.

One volume is devoted to the text, two to stereograms. The latter are very beautiful, but they of course present only a false stereoscopic effect. We doubt if this method of reproduction has any advantage at all. With the ordinary ophthalmoscope the fundus is viewed with one eye only, and no stereoscopic effect is obtained. Why therefore simulate such effect by artifice, since greater verisimilitude cannot thereby be obtained? If the drawings had been on a larger scale they would have been worthy rivals of the best to be found in any ophthalmoscopic atlas.

The text opens with an elementary chapter on the examination of the eye, and is followed by chapters on the normal fundus, congenital anomalies, affections of the choroid, sclerosis of the retinal vessels and retinal hæmorrhage, angiopathic retinitis, closure of the retinal vessels, detachment of the retina, degeneration of the retina, miscellaneous affections of the retina, optic neuritis and optic atrophy, myopia, glaucoma, and intraocular and orbital tumours. Whenever possible a stereogram is used as a peg upon which to hang an exhaustive account of each condition. So far as individual sections are concerned the descriptions are full, accurate, and well presented. Particular attention is devoted to pathology, of which Dr. Oatman is well known to be an ardent student. The photographs of pathological conditions are amongst the best which we have seen and have been beautifully reproduced. In many cases the records show evidence of original research and many more or less complete bibliographies of the literature are given.

The chief criticism to be advanced against the text is the inequality of the treatment of the subjects. Some of the accounts are exhaustive, others scanty, and lacunæ are not wanting. The fault is serious in a treatise intended for the use of students, who are thus liable to obtain a wrong perspective. Yet the work is well worthy of a place in every ophthalmological library and will often be referred to with profit by elementary and advanced students alike.

LIBRARY TABLE.

Atti del I° Congresso Italiano di Radiologia Medica. Pavia: Mattei and Co. 1914. Pp. 246.—We have received a copy of the Transactions of this Congress held at Milan in October, 1913, by the Italian Society of Medical Radiology. It contains the opening address of the President, Professor Augusto Righi, on the Nature of X Rays, in which he puts forward the theory that these rays are of the same nature as light rays, and hence are manifestations of electro-magnetic waves propagated in the ether. There are four important papers: one dealing with the practical application of high intensities of X rays, by Professor V. Maragliano, and another, by Dr. A. Busi, on X ray investigation of the skull, comprising fractures and the presence of foreign bodies, lesions secondary to changes in the interior, with special reference to enlargement of the pituitary body, of which he gives details of several interesting cases. These show that the various processes which produce more or less marked changes in the sella turcica are: (1) intracranial diseases which cause a gradual increase of pressure, such as cerebral tumours in general and chronic hydrocephalus; (2) supra- and intra-sellar tumours, comprising isolated chronic hydrocephalus of the third ventricle and chronic hydrops of the cisterna chiasmatis; (3) various diseases of the sphenoid and aneurysm of the internal carotid in the sigmoid groove; and (4) enlargements of the pituitary body. Other sections refer to changes in the skull in connexion with otology, ophthalmology, and odontology. Dr. P. Tandoja contributes a compendious paper on the radiology of the intestines, which should prove a valuable guide to those who make a special study of this branch of the subject. The appearances of the normal duodenum, small intestine, and colon are separately described and contrasted with the various pathological changes to which they are each subject. The last paper is devoted to Roentgen and radium therapy in gynæcology, by Professor M. Bertolotti. The publication concludes with 78 shorter communications on a variety of subjects, the last of pathetic interest, being an account of the necropsy performed on one of the most esteemed workers in this branch of science, Emilio Tiraboschi, who succumbed in December, 1912, to an aplastic form of pernicious anæmia caused by exposure to X rays, the destructive effect of which he had never protected himself against.

Lead Poisoning from the Industrial, Medical, and Social Points of View. By Sir THOMAS OLIVER, M.A., M.D. Glasg., F.R.C.P. Lond. London: H. K. Lewis. 1914. Pp. 294. Price 5s. net.—This little book contains the lectures delivered by the author at the Royal Institute of Public Health and treats of the various modes by which lead gains entrance into the human system, how its presence affects the organism, and how it may be got rid of. Notwithstanding the great extent to which lead is used in various industrial processes, a great reduction in its evil effects has been brought about by the inspection and regulations of the Home Office. Among the industrial processes especially dealt with are lead smelting, manufacture of red lead and white lead, china and earthenware and pottery, electrical accumulator works, printing and type-founding, plumbing, dyeing, glass-making, tinning, diamond cutting, and house painting. The modes of entrance of the poison, the onset of symptoms, the physical signs and other phenomena, and the special effects of lead on vision and the nervous system, as well as its peculiar effects in the female and its effects on motherhood, are included, and the treatment, preventive and curative, is described. The book closes with the various factory and workshop orders relating to the subject that have been promulgated. There is an adequate index. The work will prove of service to those especially interested in the subject.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLVIII., No. 5. September, 1914. Cambridge University Press. Pp. 357–464. Price 7*s.*—The Mechanical Factors which Determine the Output of the Ventricles, by S. W. Patterson and E. H. Starling. After an interesting and explanatory introduction the method used is described. Practically the preparation employed is the now well-known heart-lung preparation which was obtained from dogs weighing from 4 to 6 kilos. The authors find that: 1. The output of the heart is equal to and determined by the amount of blood flowing into the heart, and may be increased or diminished within very wide limits according to the inflow. 2. The maximum output may amount to three litres per minute for a heart of 56 grammes. 3. With a minimal inflow the venous pressure on the two sides of the heart may be zero, and with increasing inflow rises at first only slightly so long as the amount of blood flowing in is not more than sufficient to exert a minimal distension on the relaxing ventricles. 4. The greater the arterial resistance the higher will be the venous pressure for any given inflow. 5. The greater the arterial resistance the sooner will the inflow attain its optimum and the output its maximum. 6. If the inflow is maintained constant alteration of rate of heart-beat does not alter the output per minute. 7. The greater the pulse-rate the larger may be the venous inflow without raising venous pressure beyond the optimum. The maximum output therefore increases with increased rate of heart-beat. 8. The optimum venous pressure is the amount necessary to produce "maximal" dilatation of the heart during the period of diastole. The maximum size of the heart depends on its structural arrangements, and in the intact animal is determined by the pericardium. It probably represents the size beyond which the heart could not dilate without causing its muscle fibres to act at considerable mechanical disadvantage in raising intracardiac pressure. 9. With a constant inflow fatigue of the heart is shown by a rise of venous pressure accompanied by increased diastolic filling and mean volume of the heart, the outflow remaining constant. The statements as to venous pressure apply to both sides of the heart. When failure occurs under a maximal load either the right or the left side of the heart may fail before the other side.—The Time Relations of Acid Production in Muscle during Contraction, by H. E. Roaf. It is a well-known and long-established fact that muscular contraction causes a production of acid. The author placed small medusæ in sea water to which various indicators were added. The most successful indicator used was neutral red, in which the medusæ stain a faint pink. At each contraction of the muscular plate the colour became a deeper red and then faded again. We know that the lactic acid formed after contraction of a muscle is removed by some process requiring the presence of oxygen. The author describes his electrical method of measuring the change in hydroxyl ion concentration of muscle, for which reference may be made to the original paper. From a calculation of the time phases of the capillary electrometer used and other data the author concludes that his experiments favour the view that the increase in acidity is the cause of the shortening of muscle. Repeated stimuli lead to a fusion of electrometer curves due to increase in acidity before fusion of contractions occurs.—The Origin of the "C" Wave in the Jugular Pulse, by James M. McQueen and A. W. Falconer. The source of this wave has been in dispute. The authors agree with those who hold that it is of auricular origin, and not to the impact of the neighbouring carotid artery.—Myothermic Experiments in Salt Solutions in Relation to the Various Stages of a Muscular Contraction, by Viktor Weizsäcker. This paper is highly technical and of particular interest to physiologists. Broadly speaking, the author states that his results strengthen the theory of a chain of two different machines in muscle: (1) contraction-mechanism and (2) oxidative recovery mechanism.—Gaseous Exchange in the Decerebrate Animal, by Charles G. L. Wolf and T. S. Hele. A technical paper.—The Suprarenal Bodies and Diuresis, by Douglas V. Cow. It appears that different effects are produced by perfusing (*a*) directly through the renal arteries and (*b*) through the aorta of cats. Two sets of experiments were made, from which the author concludes that the suprarenal bodies are direct regulators of urinary activity.—The Temperature Coefficient of the Refractory Period in Nerve, by E. D. Adrian. This paper also is highly technical.

St. Mary's Hospital Gazette for October is a very interesting number. The words "War Number" in big red letters suggest its general scope. It contains an editorial note on St. Mary's and the war, from which we learn that St. Mary's men preside over half the base hospitals of London, and are represented on another. Captain W. H. Willcox, R.A.M.C. (T.F.), describes the Third London Base Hospital. Mr. Ernest Lane gives an account of the American Women's Hospital at Paignton, which on Sept. 27th received at 24 hours' notice 130 patients, mostly from Mons and Soissons, and further batches of 29 on Oct. 5th and 121 on Oct. 6th. The wounds were naturally for the most part septic on arrival, but as they were principally due to shrapnel the tracks were open, so that there was no pocketing of pus. Dr. A. Hope Gosse records the work done by the hospital yacht *Liberty*. Lieutenant W. D. Arthur writes from the forces in France, and says: "Five of our officers have gone to the front already, and of these two are killed and another *hors de combat*. These men were from our own hospital staff, civil surgeons like myself, and one of them a married man with three young children." There is also part of a letter from a late houseman at the front, who as medical officer attached to the Middlesex regiment finds his work "most congenial." There is an obituary notice of Lieutenant J. F. O'Connell, R.A.M.C., who was killed at the battle of the Aisne on Sept. 20th. The list of St. Mary's men and nurses serving in various capacities in connexion with the war occupies seven columns.

Proceedings of the Prehistoric Society of East Anglia, 1913–14. London: H. K. Lewis. Pp. 385–491. Price 3*s.* 6*d.* net; postage 3*d.*—Those who take a keen delight in digging out knowledge of the far-off ancestors of the human race by unearthing and observing and comparing their fossil remains, the implements of which they made use, and so forth (and obviously they include many medical men), will always find a fund of, to them, intensely interesting material in the "Proceedings of the Prehistoric Society of East Anglia." The issue now before us contains interesting papers on Flint Remains, by the President, Mr. J. Reid Moir, Mr. A. E. Peake, Mr. J. S. Warburton, Mr. W. G. Clarke, Mr. Alfred Schwartz, Mr. H. H. Halls, Colonel A. W. Jamieson, Mr. F. N. Haward, Mr. Reginald A. Smith, and Mr. Bellerby Lowerison. An Early Norfolk Trackway: the "Drove Road," forms the subject of a communication by Mr. W. G. Clarke and Mr. H. Dixon Hewitt. Mr. Miller Christy publishes a comment on the report of the committee on the "Red Cray Shell Portrait." Mr. Alfred Schwartz outlines a scheme for organised research on flint instruments. Mr. Walter Rye describes an East to West Trackway across Norfolk, and Lieutenant-Colonel W. Underwood gives a further review of recent advances in "palethnology." If we might venture a criticism, we would suggest to those who devote so much enthusiasm to digging out an interpretation of fossil and other remains not to go out of their way to throw unnecessary obstacles in the way of those who have to dig out the meaning of words from their component roots. The root of the Greek word for ancient is not "pal"—though the French still use *mon vieux* in a sense equivalent to my pal—but palai (Latin, palæ; bastard English, pale); consequently we suggest palæethnology.

WE have received from Mr. H. K. Lewis, of 136, Gower-street, London, a "List of Medical Journals" conveniently grouped under subjects, and giving the subscription rates. It should be of use to librarians, secretaries, and individual medical men and specialists seeking information respecting periodical publications. It should be mentioned that the list was compiled and printed before the European crisis became acute, and notice is given that journals issued in "enemy" countries cannot be supplied until the war is over.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 7, 1914.

The Wounded in the War.

THE terrific fighting throughout the western area of the war, and especially in Flanders, where the Allied Forces are disputing successfully every inch of German advance along the Belgian coast of the Straits of Dover, has resulted in an appalling death-roll and in a commensurate number of wounded. Boulogne and Dieppe are towns of hospitals, and while as far as possible their accommodation is relieved by shipment to this country, the congestion still remains, with accompanying pressure upon all the arrangements for surgical treatment and for nursing. Nor is the evacuation of the wounded from these hospitals, or from similar institutions in close communication with the districts where the actual fighting is going on, a thing to be regarded complacently as an ideal course. A medical correspondent pointed out in the *Times* at the end of last week that while the stream of wounded into Boulogne continues, as it must continue, surplus cases will be shipped across the Channel with a rapidity which will not take sufficiently into regard the fitness of the patient to stand the prolonged journey. The circumstances have altered for the better, and the correspondent of the *Times* did not take into consideration the military exigencies of the situation, and was apparently unaware of the amount of provision for the care and accommodation of the wounded which was forthcoming. But the position of Boulogne is not quite comparable with that of other towns less immediately in the line of the direct and fierce German objective. There is great need for surgical assistance in the north of France. There is a shortage of hospital equipment in many of the towns whose position in the rear of the Allied Forces marks them out as natural places for the reception of the wounded, and though much has been done to remedy this, and though much is daily in the doing, the fact still remains that here especially, and also in many districts where the wounded have congregated, there is urgent need of surgical assistance. And there is great difficulty in providing it.

The difficulty is outlined in letters which we publish in our present issue from Sir VICTOR HORSLEY and Dr. JAMES DONELAN. There is in our country a large body of surgeons willing to proceed at once to France and to give their services at the places where they are most required, but who may not find it easy to make their proposals fit with the organisation which the Anglo-French committee of the British Red Cross has hitherto set in motion. We can quite understand that this should be so. The British Red Cross has a very high standard to maintain, and may feel that all movements towards flexibility, if taken under its ægis, are attended with a certain measure of risk to that standard. We have reason, however, to think that a policy more favourable to those who desire to give individual help will be pursued. There is considerable intercommunication with France now, and apart from the representatives of various journals, who are largely laymen, many medical men have been into France and have seen for themselves, or have learned from the lips of French colleagues, of existing needs that could be met, but which are not being met. There are plenty of British surgeons willing to go out to the assistance of the wounded in French hospitals, and a large array of French hospitals where their services would be of the first value; and all must agree that this supply and demand should be brought at once into proper relation, so long as the methods employed do not run counter to general military policy. Dr. DONELAN, who pointed out in our columns on Sept. 26th that there were French hospitals near the front where the services of British surgeons would be welcome, has received, we learn from his letter this week, many offers of assistance, and we are sure that, if the British Red Cross Society can help him to allot these volunteers to places where they are known to be wanting, much good will ensue.

We publish this week two communications which sufficiently account for the divergent opinions on the way in which the wounded are being treated in France. Our regular Paris Correspondent, who is now with the fighting forces in the southern area, tells distinctly how it has come about that elaborately planned machinery for the prompt and humane treatment of the wounded has been defeated by the unparalleled circumstances of the war. But he shows also that the French have risen to the unexpected conditions and are coping with them successfully. A correspondent from Chambéry shows well that at an important provincial centre the first effect of the war was to deprive the town of its complement of medical men who might have succoured the wounded, but he indicates that substitutes were found, and is able to report the resulting state of affairs as satisfactory. From both these letters written on the spot it would be possible to justify some of the trenchant things that have been said of the care of the wounded during the war, but from both it is also apparent that difficulties of the gravest sort have been triumphed over to a great extent.

Annotations.

"Ne quid nimis."

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

WE publish this week a further record of atmospheric pollution as observed at 28 stations in the country. It will be seen that a wealth of valuable evidence is being accumulated which is bound to draw serious attention to an important gap in our sanitary organisation. The scheme has been well founded by the Committee for the Investigation of Atmospheric Pollution, which is responsible for obtaining regular monthly returns from the various observers. This committee will have the satisfaction of knowing, we hope in the not distant future, that when the consummation is reached, and the inexcusable pollution of the air by the smoke of our chimneys, domestic as well as industrial, is effectively suppressed, the spade work was theirs. We may, moreover, claim some share in initiating the movement, as in an annotation as far back as September, 1895, entitled "Is the Smoke Nuisances Act Properly Enforced?" we gave numerous examples of offences against the law. We suggested that the authorities should be roused to action in the matter and take immediate steps to bring to book any offenders, especially as they could avail themselves of simple means by which the production of objectionable smoke could be minimised. The Committee for the Investigation of Atmospheric Pollution are undertaking an important branch of sanitary service which should be widely appreciated.

THE DUCK AS A PREVENTER OF MALARIA AND YELLOW FEVER.

THE prevention of malaria and yellow fever by the use of animals which are the natural enemies of the mosquito does not seem to have received sufficient attention. Dr. S. G. Dixon, Commissioner of Health of the Commonwealth of Pennsylvania, has recently pointed out that the duck is one of the greatest enemies of the mosquito, and therefore can play an important part in the prevention of malaria and yellow fever. After trying the ability of fish to devour the larvæ and pupæ of mosquitoes with varied success he built two dams near one another on a stream, so that they gave exactly similar breeding grounds for mosquitoes. In one 20 mallard ducks were allowed to breed. The other was protected from water fowl, but well-stocked with gold-fish. The one remained for several months entirely free from mosquitoes, while the other swarmed with them in different cycles of life. To the infested pond ten well-fed mallard ducks were admitted. At first they were attracted by the tadpoles, but they soon noticed the larvæ and pupæ of the mosquitoes and ravenously devoured them in preference to any other food. After 24 hours no pupæ could be found, and after 48 hours only a few small larvæ. The motion of the water produced by the ducks of course drowned some of the insects, what proportion could not be estimated. For some years Dr. Dixon has been using ducks to keep down mosquitoes in swamps that would have been expensive to drain, but he never appreciated their efficiency until he made these experiments. In the work of Howard, Dyar, and Knab on "Mosquitoes of North and Central America and the West Indies" is an essay on the destruction of the mosquito and house-fly by Mr. W. Beutenmueller, who expresses the view that aquatic birds could be used for the purpose of destroying mosquito larvæ. Mr. W. Lockwood, of Boston, who has made a hobby of raising aquatic fowl, thinks that the spoon-billed duck is particularly adapted to the destruction of larvæ resting on the surface of water. While other birds, fish, spiders, batrachians, arthropods, and reptiles are all enemies of the mosquito, Dr. Dixon claims that none have the wide geographical range and the capacity of the duck for devouring large numbers of the larvæ and pupæ. Ducks can be used in ponds, swamps, both open and in jungles, and can be driven from place to place. We may point out that fish are being used for the destruction of mosquito larvæ with greater success than appears to have been obtained by Dr. Dixon. In Gambia a constant reserve of fish is maintained in some of the drains at the sea end, even in the dry season, and as required fish are transferred to other drains and private wells. More and more people are having their wells stocked with fish, and this measure proves more efficient than well covers, which must be frequently removed. Fish from the sea introduced into comparatively fresh water take some time to adapt themselves to it, but after a day or two become brisk and destroy larvæ with avidity. The number which can be destroyed is shown by the following sanitary report. A drain which had been dry for some time filled up to 90 yards from the sluice gate during high tides in April, the average depth being 4 inches. On April 23rd larvæ half-grown and over were present to the number of 2100. Eleven fish averaging 4 inches long and 5 averaging 2 inches, which had been kept some time in fresh water, were introduced at 11 A.M. Close inspection at 9 A.M. on the following morning did not show a single larva.

THE PHYSICAL SIGNS OF CARDIAC HYPERTROPHY.

IT has long been recognised that right or left-sided cardiac hypertrophy may occur; similarly, but with less clinical insistence, there may arise general cardiac hypertrophy. Right-sided hypertrophy is held to be strongly indicated when there is a well-marked epigastric pulsation, or on palpation a forcible thrust in this region; left-sided hypertrophy, on the other hand, is suggested by the presence of a local and forcible apex beat situated below and external to its normal position. These are commonly accepted clinical dicta. Later work has enabled both these clinical signs to be tested with a more searching accuracy in two ways. The form of the deflections of the string galvanometer applied to the heart (Einthoven) records, with proved efficiency, whether there is right or left-sided preponderance of ventricular action. In general these observations have borne out clinical findings; left-sided relative preponderance occurs with aortic disease (often) and interstitial nephritis; right-sided preponderance holds in most cases of mitral stenosis and in all cases of congenital pulmonary stenosis. Another method of checking clinical findings has been by careful post-mortem weighings of each ventricular mass. The technique is laborious, for the ordinary naked-eye estimations of supposed hypertrophy are wholly inadequate for accurate work. The correlation of these two methods with the clinical signs has led to some important facts, recorded by Dr. Thomas Lewis in *Heart* (1914, v., 367). In the first place clinical signs alone, though useful, are not, in a moderate number of cases, truthful. The epigastric thrust, for instance, as investigated in 53 cases, is shown to be as marked when the right ventricle is normal as when enlarged (as tested by weighing); and, again, even the local apical impulse may be due, not to left, but right ventricular hypertrophy. Secondly, in considering special valvular or circulatory conditions, it is found that whilst in most cases of mitral stenosis right preponderance exists, left may also be met with, especially when there is coexisting raised arterial tension. In aortic disease left-sided hypertrophy may or may not be present, as shown both by weighing and by the electrocardiogram. In interstitial nephritis, with raised blood-pressure, left-sided preponderance was especially prominent. The ratio L:R which is normally 1·8 (though subject to wide variation in different healthy subjects) becomes, with raised arterial tension, 2·0 or over. Dr. Lewis adds some general observations upon hypertrophy. He emphasises the need for more accurate measurements. "That changes in the mechanical condition of the circulation are the sole or even the chief causes of hypertrophy has not been proved." In man, for example, with aortic disease the increased weight of the heart may be even 280 per cent. more than normal, a hypertrophy never attainable in analogous animal experiments. Some of the largest hearts, again, are due to causes unknown. Many hearts show general hypertrophy. Finally, contrary to what would be expected, raised arterial tension produces the greatest left-sided hypertrophy when associated with mitral stenosis, more even than when associated with either aortic disease or purely renal lesions. "Evidently," as the writer says, "before we can consider our knowledge of hypertrophy in relation to valvular or renal disease to be at all complete, the number of hypertrophied hearts studied must be multiplied."

INTRATRACHEAL ADMINISTRATION OF ETHER AND CHLOROFORM.

THAT there must be certain advantages inherent in the administration of anæsthetics through a tube passed down the trachea is obvious to all who have had practical experience of the extent to which mechanical obstruction in the upper air passages is responsible for difficulties arising during inhalation anæsthesia. All these difficulties, whether from engorgement of the tongue and fauces, from spasm of these parts and sucking back of the tongue, from glottic spasm, or from mucus accumulation, are completely obviated by intubating the trachea. That this is the case has been amply demonstrated not only by the quiet conditions witnessed in the laboratory where animals are habitually anæsthetised through a tracheotomy tube, but also by the many cases in which a human patient is similarly anæsthetised after a preliminary laryngotomy or tracheotomy, as in operations for the removal of the tongue. In these cases, although there is no intubation from above, yet the upper air passages are cut out of the inhalation region just as they are when the trachea is intubated, and with a similarly gratifying result as regards freedom from all obstructive difficulties. To gain these advantages by intubating the trachea there are, however, certain obstacles to be overcome, and it remains an open question whether for ordinary routine work the gain justifies the extra time, labour, and apparatus required. The first obstacle is to be found in the difficulty that often arises in passing a catheter down the trachea. This difficulty is well illustrated by some of the cases described in Mr. Rupert Jones's article, which appears in our columns this week (p. 1087). There it will be seen that in one case as much as 30 minutes was expended in attempts to catheterise the trachea; in other cases there was considerable difficulty; in one the feat was found impossible. These difficulties diminish, no doubt, to a large extent with extended practice, but they are to be reckoned with, and particularly as they arise in the very cases where tracheal insufflation is otherwise so advantageous—for example, in cases of goitre and of removal of the tongue for cancer. A scrutiny of Mr. Jones's cases, as well as experience with apparatus somewhat of the type that he employed, leads us also to the conclusion that besides much practice in passing the catheter there is necessary for complete success in this work an apparatus of considerable complexity. The apparatus must provide for a sufficiently strong vapour percentage of ether, and must work at least fairly silently and with perfect regularity, besides providing the right amount of pressure and warming for the vapour. This question of pressure leads to reflections upon a second article which we publish this week (p. 1085), in which a method is described for the intratracheal administration of chloroform. It must be remembered that there is a distinct difference between merely supplying a vapour for the lungs to inhale, as is commonly done, for instance, when chloroform is given from a Junker's inhaler into a tracheotomy tube, and pumping vapour into the lungs at a positive pressure. Now it is the former process which Mr. W. Dakin Mart imitates in his intubation apparatus, but it is the latter which is the essential feature of intratracheal insufflation, as practised by Dr. F. E. Shipway and others who are exponents of the method. Moreover, we must entertain grave doubts as to the wisdom of seeking to imitate with chloroform the process which is safely carried out with ether, even in spite of the immediate opportunity afforded for the very efficient application of artificial respiration. It is just because tracheal insufflation renders possible the use of ether in many severe cases which had hitherto to be managed with chloroform that this proceeding has become so valuable an adjunct to the more usual methods of anæsthesia. For extensive operations within the thorax and for many of the severe cases in which there is likelihood of free bleeding into the mouth and pharynx intratracheal insufflation supplies us with a most efficient procedure that discountenances to a large extent the dangers inherent in these operations when undertaken with the use of chloroform.

THE WIDENING FIELD OF PRACTICAL PSYCHIATRY.

PSYCHIATRY is both theoretical and applied. Practical psychiatry consists in the application of knowledge gained from the study of mental disease to the problems of its prevention and cure in the individual and in the community. We believe it is becoming increasingly evident that practical psychiatry is in reality concerned with a social problem, the solution of which demands organisation and methods that are essentially of a public or semi-public character. In days gone by the main object of practical psychiatry was the seclusion of the individual no longer responsible for his actions; gradually it came to be recognised that in addition to caring for and feeding him definite medical treatment with a view to ultimate cure was an object worthy of attention, a goal worthy of aim; scientific study of the material proceeded *pari passu* with this adoption of modern therapeutic measures. Now, however, the time is ripe for further extension of the problem. It must be dealt with on still broader lines. Just as now the community as a whole is disposed to seek its own sanitary welfare, and to devote public funds to this end rather than depend upon private philanthropy, so the community is beginning to recognise that mental disease, as well as crime and poverty, must be dealt with socially—that is to say, that the attention hitherto more or less concentrated on institutional treatment must be directed also to the social conditions under which mental disorders arise. In an eloquent address by Dr. William L. Russell, superintendent of Bloomingdale Hospital, New York, to be found in the annual volume of *Transactions of the American Medico-psychological Association*, the importance of these developments and extensions in the treatment of the mentally afflicted is fully emphasised. In New York State earlier and better attention to this type of patient, both before and after institutional treatment, has resulted in definite gain to the individual. Instead of the relieving officers the medical officers of health are responsible for the handling of cases of mental disease. In the general hospitals of the large cities psychopathic departments and wards have been organised where prompt medical treatment may obviate any necessity of the patient's being transferred to an asylum. Mental out-patients' departments are found in many hospitals and dispensaries. The importance of domestic and social readjustment in most cases of mental disease cannot be over-estimated. Through the agency of what is called the social service department the domestic and personal difficulties under which the patients may labour are investigated and as far as possible compensated, and thus the application of what has been learned about the nature and causes of insanity is directed to its prevention. In this connexion we may call attention to a recently issued report of the work of the out-patient department of the new Henry Phipps Psychiatric Clinic at the Johns Hopkins Hospital in Baltimore. Dr. Macfie Campbell, who writes the report,[1] says that in nine months 543 patients presenting symptoms of mental disorder varying in type and degree have been examined. The cases have ranged from the subjects of definite organic brain disease to children with bad tempers. Dr. Campbell finds the work of his social service department invaluable, and a perusal of his report will go far to convince the reader of the bearing of practical psychiatry on many vital interests of the community. The scientific interest of the cases is of course considerable, but their treatment cannot be satisfactory unless and until it is recognised that the trouble for which the patient or his friends seek advice and relief is often what may be called a "disorder of adjustment." In a case of mental disease the primary disturbance may be at a level of the patient's activity little suspected, unless the whole matter of his environment is thoroughly gone into. In this way, as Dr. Campbell says, important social and educational issues are raised, and even where in the individual case little can be done the thorough study of the disorder in its complete setting may contribute data of value in relation to the mental hygiene of the community. This is the aspect of practical psychiatry that is bound, we feel sure, to impress itself more and more on the physician, and that the community as a whole will for its own sake sooner or later have to face.

THE HUNTERIAN SOCIETY AT THE BARBERS' HALL.

THE Worshipful Company of Barbers should possess more than ordinary interest for members of the medical profession, for in the year 1461 it was incorporated under a charter of Edward IV. with the right of its members to practise surgery, and what is said to be the first licence extant granted to any surgeon in England to practise surgery was given by it in 1492. In 1541 the Barber-Surgeons' Company was incorporated by Act of Parliament with the Company of Surgeons of London, a union which continued for upwards of 200 years.[1] When in 1745 the control of surgical practice in London and the education of practitioners with the accompanying endowments passed from the Company of Barber-Surgeons to the College of Surgeons of London (now the Royal College of Surgeons of England) the ancient Hall of the Barber-Surgeons in Monkwell-street remained, together with its contained records and art treasures, in the possession of the Worshipful Company of Barbers. Largely through the offices of Dr. Glover Lyon the Barbers' Company has now placed its handsome Council Chamber at the disposal of the Hunterian Society for its meetings, and it was there that on Oct. 28th Dr. Lyon delivered his presidential address before the Society. He gave an interesting account of the Barbers' Company and of its share in the evolution of the art and practice of surgery in England, and quoted from the old records many details illustrative of the punishment of quackery in the reign of Richard III., the state of surgery in the wars during Henry VIII.'s reign, the punishment for malpractice in 1635 (a case in which "Mr. Doctor Harvye," the discoverer of the circulation of the blood, figures as an "expert medical witness"), and of two cases of resuscitation after hanging, which occurred in the Hall respectively in the years 1587 and 1740. But the most interesting part of the address consisted in Dr. Lyon's description of, and comments on, the pictures and other objects of interest belonging to the Company, which were all exposed for the subsequent inspection of the visitors. Dr. Lyon paid a justly deserved tribute to the courtesy of the Company, which gladly affords opportunities of inspection to those who are likely to be appreciative of such antiquarian and artistic treasures. It is undoubtedly a great boon to lovers of such relics to examine the pictures at leisure away from the chilling atmosphere of a public gallery, and to handle the cups and other objects instead of merely gazing at them through glass covers. Not the least interesting of the exhibits was the original illuminated book of ordinances, which dates from the first half of the sixteenth century. Among the paintings are Holbein's celebrated picture of King

[1] For an admirable account of the relations of the Barbers' and the Surgeons' Companies see the address by Sir Rickman J. Godlee on the Origin and Growth of the Royal College of Surgeons of England in THE LANCET of Nov. 22nd, 1913, p. 1443.

Henry VIII. granting a charter to the Company in 1541, all the personages represented therein being celebrities. To three of them Dr. Lyon gave special mention—viz., John Chambers, Henry VIII.'s physician and Archdeacon of Bedford, one of the founders of the College of Physicians; Dr. Butts, mentioned by Shakespeare in *Henry VIII.*, who attended Anne Boleyn and was sent by the King to Wolsey after his disgrace; and Thomas Vicary, five times Master of the Company, serjeant-surgeon to Henry VIII., Edward VI., Mary, and Elizabeth, chief surgeon at St. Bartholomew's Hospital, and author of "The Englishman's Treasure," said to be the first work on surgery published in English. Other pictures were portraits of Sir Charles Scarborough, of Edward Arris, founder of the Arris lectures, Sir Charles Bernard, serjeant-surgeon to Queen Anne, and Sir John Tweedy, who has linked in his person for a time the two divided companies, having been Master of the Barbers' Company as well as President of the Royal College of Surgeons of England. The Company's plate includes the silver gilt cup presented to the Company by Henry VIII., a characteristically graceful tankard presented by Charles I., and an appropriately solid flagon presented by the Roundhead professor of surgery, Thomas Collins. Finally, there is the Boscobel cup presented by Charles II., which again is an example of grace and instability.

THE ACTION OF DRUGS ON PLANTS.[1]

By Professor J. C. Bose, M.A., D.Sc., C.S.I., C.I.E.,
PRESIDENCY COLLEGE, CALCUTTA.

In the scientific study of the effect of drugs we should aim to get at the very root of the matter, in discovering the fundamental reactions of drugs on the simplest protoplasmic mechanism of the plant, for it will be admitted that it is only by the study of the simpler phenomena of irritability in the vegetal organism that we can ever expect to elucidate the more complex physiological reactions in the animal tissues. In connexion with this I may cite one of our greatest living authorities, whose work has become classical. In his standard work on medicine Sir Lauder Brunton expresses his deliberate conviction that scientific investigations regarding the effects of various drugs on the animal could not be regarded as satisfactory until we succeeded in discovering their effects on living organisms as a whole, including the plant.

I shall first demonstrate the similar physiological characteristics in vegetal and animal organisms, and next speak of the effects of various stimulating and depressing agents, such as a constant electrical current, various drugs, narcotics, and poisons, on the contractile, the conducting, and the rhythmic tissues of the plant. It will further be shown how the normal effect of a drug on the plant is profoundly modified by two other factors. The first of these is the influence of dose or strength of appreciation. The second factor of modification is the change induced in the tissue by the cumulative action of stimulus, in consequence of which the response of the organism undergoes a complete cyclic change. Consideration of these questions will probably throw much light on various anomalies met with in medical practice.

Assuming that plant tissues respond to the characteristic action of different drugs, yet the physiological change induced will elude our visual scrutiny. To take an extreme case, we find that it is impossible by mere inspection to distinguish between plant specimens one of which is alive and the other killed. We have then to discover means by which the plant itself is made to reveal its internal condition, and changes in that condition by characteristic signals recorded by it. Our success in devising such a method will enable us to determine whether a given drug causes an excitatory or depressing effect on the plant.

Plant Script.

As regards the possibility of revealing internal changes in the plant the conceivable way of doing so is by the detection and record of the response of the organism to a definite testing shock. If we can find out in the plant the relation between the stimulus or response we shall be able to determine its state of vitality at the moment. In an excitable condition the feeblest stimulus will evoke an extraordinarily large response; in a depressed state even a strong stimulus will evoke only a feeble response; and at the onset of death there is an abrupt end of the power to answer at all. Thus by means of testing blows we are able to make the plant itself reveal those invisible internal changes which would otherwise have entirely escaped us. We may, as we shall see, employ different methods of recording the response of the plant. The most evident is the method in which the answer is given in the form of mechanical movement.

Mechanical Response of Plant.

At the point in the leaf of the so-called sensitive plant, Mimosa, there is a cushion-like mass of tissue known as pulvinus. Under excitation the parenchyma in the more excitable lower half of the pulvinus undergoes contraction, in consequence of which there is a fall of the leaf. The sudden movement constitutes the mechanical response of the leaf. By the invention of different types of recorders I have succeeded in making the plant itself write an answering script to a testing stimulus, and in order that the results obtained should not be influenced by any personal factor arrangements have been made that the plant attached to the recording apparatus should be automatically excited by a stimulus absolutely constant, should make its own responsive record, going through its own period of recovery, and repeating the same cycle over again without assistance at any point on the part of the observer.

Similarities of Mechanical Response of Plant and Animal.

In the response of animal tissue it is found that a single stimulus, by itself ineffective, becomes effective upon repetition. The same is found to be the case in plant tissue. Thus, in a particular experiment, while an electrical stimulus of intensity 0·1 was singly ineffective, it became effective after being repeated 20 times. It is found, moreover, that this additive effect is, within limits, strictly quantitative. As in the case of the animal tissue, so also in Mimosa, the response is abolished at a sufficiently low temperature. With rise of temperature the amplitude of response is increased and the period of recovery shortened. The effect of load on the response of Mimosa is similar to that on the contractile response of muscle. In both, under increasing load, the height of response undergoes a progressive diminution, with shortening of the period of recovery. Within limits the amount of work performed by the muscle increases with the load. The same is true of the work performed by the pulvinus of Mimosa. The latent period is in general shorter under greater intensity of stimulus, the value becoming constant above a maximal stimulus. The shortest value in the pulvinus of Mimosa is 0·06 second, and I can show a pair of records giving a value of 0·109 second. A rise of temperature shortens the latent period. Under fatigue, on the other hand, the latent period is very much prolonged. When excessively tired the plant temporarily loses its power of response. In this condition the plant requires at least half an hour's period of absolute rest to regain its equanimity. In all these reactions we observe a remarkable parallelism with contraction phenomena in the muscle.

[1] Abstract of a lecture delivered before the Royal Society of Medicine on Friday, Oct. 30th.

Death Spasm in Plants.

The electrical response of galvanometric negativity is abolished on the death of the plant. When the plant is subjected for a time to a temperature of 60° C. the electrical response disappears. This temperature is therefore fatal for most plants. In order to determine the exact death point I subjected Mimosa and various other plants to a gradual rise of temperature. This is attended by a progressive, expansive, or erectile movement; at the critical temperature of 60° C., however, the movement of expansion is suddenly reversed to a spasmodic excitatory contraction. The reversal takes place under standard conditions at or about 60° C.; after this the response of the plant is permanently abolished. The death-record is a V-shaped curve, the sharp point of inversion being the death-point. After death repetition of this experiment shows no further inversion. That this spasmodic contraction is a physiological phenomenon is further seen from the fact that the death point as determined from the inversion of the curve is lowered under physiological depression. Thus, fatigue will lower it to an extent depending upon the degree of fatigue. In a certain instance the death point, owing to fatigue, was lowered from the normal 60° C. to 37° C. Previous administration of dilute poison lowered the death point in another case by 18° C. Finally, I have shown that all excitatory reactions have as their concomitant a sudden electrical change, of a definite sign, and it is very significant that at the critical temperatare of 60° C. there occurs a sudden electrical discharge in the plant, the direction of the current being dependent on the differential excitabilities of the tissue.

Demonstration of Nervous Impulse in Plants.

The nervous character of impulse in plants has been demonstrated by me through various crucial tests. As in the case of the animal, so also in the case of the plant, the excitatory impulse may be arrested by the action of an electrotonic block. As long as the current is maintained so long is the impulse arrested; on the cessation of the blocking current, however, the conducting power is immediately restored. Local application of poison is found to arrest permanently the excitatory impulse through the poisoned tract.

Conducting Power of Nerve and its Variation.

We have seen how the physiological characteristics of the excitatory impulse in the plant are similar to those of nervous impulse in the animal. Under certain conditions the animal nerve undergoes changes leading to paralysis. In such a case a cure may sometimes be effected. The problem here is to impart to an ineffectively conducting tissue a better conducting power. This power of conduction or its absence is ultimately dependent on obscure molecular modifications. Discovery of parallel phenomena in the plant will undoubtedly prove of importance.

Induction of Artificial Paralysis and its Cure.

An interesting experiment relates to the artificial induction of temporary paralysis. When localised cooling is applied to a part of the petiole of Mimosa, the conduction of excitation through that portion becomes greatly delayed, till with sufficient cooling there is an actual block to the transmission of excitation. Thus it is possible by applying a fragment of ice to cause local paralysis of the conducting power of the petiole, which persists for over an hour, even after restoration of the tissues to the normal temperature. It is extremely suggestive that I was able under these conditions quickly to restore the conducting power by application of electrical shocks of moderate intensity to the paralysed region. Too strong a shock was, however, found to be highly detrimental.

Canalisation of Conducting Path.

In plant experiments I find a very significant result as regards the power of stimulus to fashion its own conducting path. Thus a plant carefully protected under glass from the stimulating buffets of the elements looks sleek and flourishing, yet as a perfect organism proves defective. Its conducting power is found to be in abeyance, though the motile organ exhibits its normal power of contraction. Anatomically the conducting elements are present, but from want of use they remain functionally inactive. Now in this condition it is very interesting to watch the growth of conducting power under the influence of stimulating blows. There is at first no transmission; after a time excitatory impulse begins to be initiated. Continued stimulation enhances the conducting power to a maximum. The concluding part of this process can be illustrated in the records.

Control of Nerve-conduction.

What is the change of the tissue which brings on paralysis? What is the molecular condition which confers conducting power on a nerve? These are very obscure problems, and any investigation calculated to throw light on the subject will undoubtedly prove of the highest importance, not only in theory, but also in practice. The nerve may have been rendered abnormal in two different ways. In one case it may have become extremely sluggish in transmitting an impulse. In the other case it may have become so hypersensitive as to transmit the feeblest excitation with intolerable intensity. In restoring the nerve to a normal condition we want to augment the conducting power in one case or arrest it in the other. A man who constantly uses the telephone has it in his power, by a simple process of switching on and off, to keep the circuit open or closed to the calls he receives, according as the message is pleasant or unpleasant. Can he similarly have the same control over the conducting system which exists within himself? Is it possible for him to augment or inhibit the nervous messages?

The phenomenon of excitation may be regarded as a process of molecular upset caused by stimulus, and the transmission of excitation as the propagation of the molecular disturbance. The phenomenon of molecular upset we may simply picture by means of a row of standing books. A certain intensity of blow applied, say, to the book on the extreme right would cause it to topple over to the left, hitting its neighbours and causing them to fall in succession. If the books have previously been slightly tilted towards the left, a disposition would have been given to them which, by facilitating the fall, would accelerate the speed of transmission. Conversely, an opposite disposition would retard or arrest the movement. Thus by means of a directive or polar force we may induce a molecular predisposition which would enhance or retard the speed of the disturbance according to the directive action, positive or negative, of the polar force. It may thus be possible to discover some polar force which, by inducing characteristic molecular dispositions, would enhance or retard the conduction in a nerve, according to the direction of the acting force.

So much for theory; its value must be judged by practical results. It may be briefly stated here that, acting on the principle that has been described, I have been successful in inducing at will and by turns two opposite molecular dispositions in the conducting tissue of the plant. When the polar force was maintained in a positive direction the speed of the excitatory impulse was enhanced in a remarkable manner. The nervous impulse could on the other hand be increasingly retarded, and finally arrested, by reversing the direction of the force and increasing its intensity. These *supra* or *a*-conducting states were maintained as long as the nerve was subjected to the action of the polar force acting in positive or negative direction.[2]

I have referred to the conducting tissue of the plant as a *nerve*. The use of this term has, I think, been justified by the remarkable similarities of reactions between the conducting tissues of the plant and animal under varied conditions. Perhaps the crucial test of a theory may lie in the power which it gives of predicting unknown phenomena, the predictions being afterwards fully verified. Believing in the identity of characteristics of plant and animal nerves, I applied the same polar forces which I found to be so effective in my plant experiments to the nerve of the frog, and it was a matter of intense gratification to me to find that by employing the same methods I could exalt or inhibit at will the conducting power of the experimental nerve. The importance of this investigation must be obvious to all. Its success further proves the importance of physiological investigation on plants in elucidating intricate problems of animal physiology.

Similarities between Rhythmic Pulsations in Plant and Animal.

In *Desmodium gyrans*, or the telegraph plant, the small lateral leaflets exhibit automatic pulsations. I find that the characteristics of the rhythmic tissues in the plant exhibit surprising similarities to those of the cardiac tissue in the animal. The down movement of the leaflet is quicker and corresponds to the systolic movement of the heart. The maximum rate of this down movement is 0·9 mm. per second. The diastolic or up movement is much slower, its maximum rate being 0·56 mm. per second. The pulsating activity of the detached heart of a frog can be maintained for long periods by subjecting it to intercardiac pressure. Similarly the activity of the detached leaflet of *Desmodium* can be renewed by the application of internal hydrostatic pressure, after which the pulsation can be maintained uniform for many hours. The cardiac tissue of the animal has a long refractory period. The tissue takes no account of the stimulus which falls within the refractory period. This is also characteristic of the response of the rhythmic tissue of *Desmodium*. Rhythmic tissues, animal and vegetable alike, are incapable of tetanus. The pulsating leaflet of *Desmodium*, like the pulsating heart, is more susceptible to excitation at diastole than at systole. An extra pulsation is induced in both by an induction shock, applied during the diastolic phase.

By the application of Stannius's ligature the pulsation of the heart is arrested at diastole. A similar arrest at diastole is found to take place in the pulsation of *Desmodium* by the application of a ligature immediately below the motile organ. The arrest takes place either at once or after one or two vigorous beats. Similar effects are also obtained by making a cut, after suitably supporting the leaflet. While the leaflet is in the condition of this arrest it is often possible to renew the pulsation by the stimulus of an electrical shock. The effect of lowering of temperature on the rhythmic pulsation of *Desmodium* is similar to that on the pulsation of a frog's heart. Lowering of temperature enhances the amplitude, but reduces the frequency of pulsation of both. A rise of temperature, on the other hand, causes enhanced frequency and diminished amplitude of pulsation. The pulsation of the beating heart may be inhibited by the stimulation of the vagus nerve. The rhythmic pulsation of *Desmodium* leaflets may similarly be inhibited by applying electrical stimulation at some distance from the pulsating organ.

Effect of Chemical Agents on the Response of Plant Tissue.

For this investigation a series of uniform responses is first obtained under uniform stimuli. After the application of the given agent another series of responses is once more obtained under the same stimuli as before. The variation of amplitude of response then gives an indication of the excitatory or depressing action of the agent. The plant is intensely susceptible to the impurities present in the air. The vitiated air of the town has a very depressing effect. According to popular science, what is death to the animal is supposed to be life for the plant; for does it not flourish in the deadly atmosphere of carbonic acid gas? In reality the plant gets suffocated just like a human being. Only in the presence of sunlight is this effect modified by photosynthesis. In contrast to the effect of carbonic acid, ozone renders the plant highly excitable. Sulphuretted hydrogen, even in small quantities, is fatal to the plant. Chloroform acts as a strong narcotic, inducing a rapid abolition of excitability. The ludicrously unsteady gait of the response of the plant under alcohol could be effectively exploited in a temperance lecture! Equally remarkable are the effects of drugs on rhythmic tissues of plants. As regards the action of ether, the effect of very diluted vapour is generally to induce a transient exaltation, followed by depression and arrest of pulsation. If the leaflet be subjected to strong vapour and if the application be prolonged the arrest is permanent. But if diluted vapour be employed and fresh air substituted immediately after the arrest, then there is a slow revival of pulsation. The effect of chloroform is similar to that of ether, its reaction, however, being far more toxic; a slight access in the application is attended by a permanent arrest of pulsation.

This and numerous other reactions exhibit the remarkable similarity in the effect of various chemical agents on the animal and vegetable tissues. A very striking characteristic is the antagonistic reaction of acid and alkali on the animal heart. Application of very dilute acid induces in the heart an atonic reaction, in consequence of which there is brought about an arrest of pulsation in the relaxed or diastolic condition. The action of dilute alkaline solution is the very reverse of this—namely, a tonic contraction and arrest in systole. I find these effects repeated in an astonishing manner in the pulsation of *Desmodium*. The internal application of dilute solution of lactic acid is seen to induce an arrest in a state of diastolic relaxation. The application of dilute NaHO solution, on the other hand, induces exactly the opposite effect—i.e., an arrest at systolic contraction.

---

[2] The detailed account of this investigation has recently been communicated to the Royal Society.

Effect of Dose.

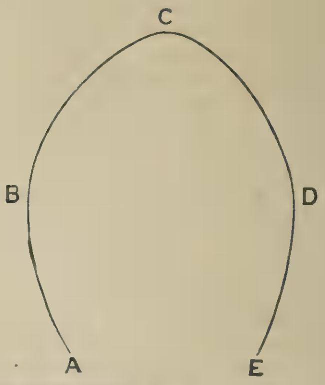
Another striking result that came out in my investigations on plant reactions is the modification of effect brought on by the strength of the dose. Thus, a poisonous reagent which caused depression or death was found to act as a stimulant when administered in minute quantities. As regards application of electrical current in medical practice, it is assumed that Pflüger's law, that it is the kathode that excites and anode that causes depression, is universally applicable. I find, however, that here too the strength of the current is a very important determining factor. Though the application of the anode causes depression with moderate currents, the reaction is completely reversed when the intensity of current exceeds a certain limiting value.

The Molecular Cycle.

We have seen how two precisely opposite results may be brought about by an identical drug or by an electrical current, owing to the varied strength of applications. There is, however, still another obscure factor which creates great perplexity. A given agent may cause a certain effect on one individual and an altogether different effect on another—"what is one man's meat is another man's poison." This difference is considered in some mysterious manner to be due to the varied constitutions of the individuals. As a concrete example I may cite the different reactions given by three batches of seedlings primarily similar. These were kept for some time under three distinct conditions and afterwards subjected to the action of a given dose of dilute poison. The first batch succumbed to the poison immediately; the second struggled for a time against it, recovered, and exhibited a moderate rate of growth afterwards. But the third batch was actually stimulated by the poison and demonstrated this by invigorated growth. Why should we find this difference? We must remember that the living tissue is not merely a mass of inert matter, but is a complexus of matter and energy held latent. The tissue may thus exist under widely different conditions, according as to whether it has been rendered active by the stimulating influence of its environment or reduced to a state of lethargy through being deprived of this. The source of stimulus here referred to includes every cause, internal or external, which brings about excitation. From the normal state of vigour the condition of the tissue may, according to circumstances, be carried to two opposite extremes—the state of inanition, through lack of stimulation, and the state of exhaustion through excess of stimulation. Between these two extremes are numerous gradations of tonic condition in the living tissue, these being determined by its past history; and it is impossible to predict what the answering reaction of the organism will be unless we know the exact position of the tissue in the scale of tonicity.

How then are we to obtain some measure of this obscure internal condition? There are two conceivable ways in which this could be attempted. One, by the study of outward posture or appearance of the organism; and second, by the character of its answers to testing shocks. A trained observer may be able to draw his inferences more or less accurately from outward appearances, but with plants we can depend on something more definite than this rule-of-thumb procedure. In the most favourable tonic condition of Mimosa, for example, the leaf is held out at a certain angle determined by the tonic contraction of the tissue. When the plant is kept completely isolated from all sources of stimulation it grows atonic, the tissue becomes relaxed, this being outwardly exhibited by the abnormally erect posture of the leaf. The plant is brought once more to a normal condition when subjected to the action of stimulus, the leaf once more occupying its normal outspread position. Under further stimulation the contractile movement reaches a limit, and when stimulation is carried to excess the contractile movement of fall is reversed into erectile movement of relaxation. If we had attached a recording lever we should have found a complete curve traced, something like Fig. 1.

FIG. 1.

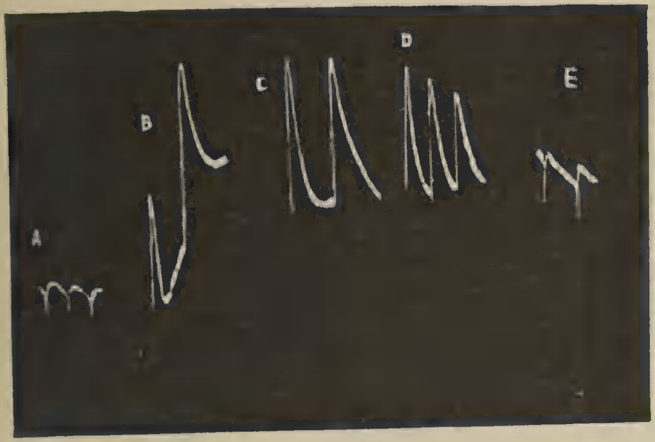


Characteristic cyclic curve showing growing contraction brought about by increasing stimulus from atonic A to C through subtonic B; subsequent reversal under over-stimulus, D moderate, E excessive fatigue.

In the study of this curve it should be remembered that on account of the method of record employed the up-movement of the leaf is shown by the descent of the curve and *vice versâ*. These outward manifestations are the expressions of internal molecular change of a physico-chemical character, and the cyclic curve representing the varied conditions of the tissue I shall refer to as the cyclic molecular curve. It will be seen from the diagram that a point in the ascending has a corresponding point in the descending curve. From this we can see how liable we are to draw a wrong inference from exclusive reliance on outward appearance or posture; for example, the parallel relaxed positions of A and E may have been brought on by two diametrically opposite conditions—i.e., extreme atonicity as at A, over-fatigue as at E. In order to restore the tissue to the normal the aim should be to bring it to the optimum condition C. For this diametrically opposed treatments are necessary, depending on the question of whether the tissue is at A or E condition. If it be at A stimulation is necessary, if at E rest or sedative treatment. But if we mistook E for A and applied further stimulation the case would have ended fatally through extreme exhaustion, while the other mistake would have been equally unfortunate for the plant, which would have met an untimely end through excessive inanition.

Turning next to the second method by which the changing condition of the tissue may be found from the progressive modification of replies to a testing stimulus, it is extremely interesting to find that corresponding to the molecular cycle which has been referred to there is a concomitant cyclic variation of response. In Fig. 2 I have given the characteristic responses of the tissue under varying molecular conditions typical of A, B, C, D, and E. I may say here that these results have been verified by experimenting on various kinds of tissues, the methods of investigation employed being so different as the electrical and the mechanical.

FIG. 2.



Typical responses under different molecular conditions, A, B, C, D, and E.

In describing the changes of response corresponding to changes in the molecular condition of the tissue, I shall for the sake of simplicity designate all normal response by contraction or by galvanometric negativity, as the *negative* response; its converse—i.e., response by relaxation or galvanometric positivity—will be termed *positive* response. Beginning with the case of extreme subtonicity corresponding to the point A in the cyclic curve, we find a maximum variation from the normal, the response being abnormally *positive*. Continued stimulation improves the general tone from a condition of relaxation to a growing tonic condition and converts abnormal positive to normal negative. At the phase corresponding to B the condition of subtonicity is moderate; stimulus removes the inertness and confers on it an increasingly better tone. Hence the characteristic response at this stage is a staircase enhancement culminating in the optimum condition C. The highest point of the molecular cycle is thus reached. Further stimulation, strong and long continued, completes the other half of the cycle, now of descent. During this descent the response at first undergoes a change from negative to less negative; that is to say, there is an appearance of fatigue. Again, under excessive stimulation the response may decline to zero, or even undergo a reversal to abnormal *positive*. As in the characteristic curve so also in the series of responses, the two halves of the cycle are so strangely alike, one being as it were the reflection of the other. The cycle begins with extreme subtonicity due to lack of stimulation and ends with exhaustion brought on by excessive stimulation. The starting-point of the one may be supposed to meet the end of the other in a common fatality. But though the one half thus mimics the other, there is as it were a polar difference between the two by reason of the difference in their past histories, necessitating treatment which must be diametrically opposite according as the tissue happens to occupy the beginning or end of the cycle.

Thus it is clear that the progress of medicine may be greatly facilitated when the attention of investigators is drawn to the importance of the molecular aspects of the phenomena with which they have to deal. Thus in examining the action of drugs a threefold question is seen to rise. It must first be determined what is the nature of the reaction induced by the given agent under normal conditions. The second matter of inquiry is what is the critical dose above and below which opposite effects are brought about? And finally, as the nature of the response is profoundly influenced by the position which the tissue then occupies in the curve of molecular cycle, it follows that the most important element in the application of a curative agent will be in the determination of the place of the tissue in the cyclic curve.[3]

I have given in this brief sketch accounts of various experiments which seem to bring the plant much nearer to us than we ever thought. We find that it is not a mere mass of vegetative growth, but that its every fibre is instinct with sensibility. We find it answering to outside stimuli, the responsive twitches increasing with the strength of the blow that impinges on it. We are able to record the throbbings of its pulsating life, and find these wax and wane according to the life conditions of the plant, and cease with the death of the organism. We have seen how the whole plant is made one by connecting threads, so that the tremor of excitation initiated in one place courses through the whole; and how this nervous impulse, as in man, can be accelerated or arrested under the several actions of drugs and poisons. In these and many other ways the life-reactions in plant and man are alike: thus through the experience of the plant it may be possible to alleviate the sufferings of man.

EXETER CITY ASYLUM.—At the last meeting of the Exeter city council a considerable discussion took place in reference to the recent decision of the council that the medical superintendent of the city asylum should not engage in any private or consultative work. The matter was reported in THE LANCET of Oct. 31st. Eventually it was decided that the medical superintendent should be permitted to examine, when called in as a consultant, into the mental condition of any patient residing in Exeter.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION:

Summary of Reports for Month ending June 30th, 1914.

1	2	3	4	5	6	7	8	9	10	11	12
Place.	Correspondent.	Rainfall in millimetres.	Metric tons of deposit per square kilometre during month.								
			Insoluble matter.			Soluble matter.		Total solids.	Included in soluble matter.		
			Tar.	Carbonaceous other than tar.	Ash.	Loss on ignition.	Ash.		Sulphate as (SO_4).	Chlorine (Cl).	Ammonia (NH_3).

Col. 4 includes all matter insoluble in water but soluble in CS_2. Col. 5 includes all combustible matter insoluble in water and in CS_2. Col. 6 includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Approx. 9 lb. per acre; (*b*) 2·56 English tons per sq. mile; (*c*) one gramme per sq. metre; (*d*) 1/1000 millimetre of rainfall (see Col. 3).

* No returns to hand.

THE CLAIMS OF BRITISH SPAS.

(Continued from p. 1009.)

V.—Bath.

As far back as 1904 we suggested that the fact that the Bath waters were found to be radio-active might lead to a more satisfactory explanation of the favourable action of natural mineral waters in hydro-therapeutic practice, and further inquiry has abundantly shown that the suggestion was a sound one. A consideration of the chemical constituents of the thermal waters of Bath throws practically no light on the admitted therapeutic efficiency of a course of these waters. As Sir William Ramsay has pointed out, the recorded analyses of the Bath waters show, in the main, mere ordinary constituents, most of which are present in many drinking-waters. Sulphates of calcium, of sodium, of potassium, carbonates of calcium and magnesium, are all common substances. He adds that the only unusual constituents of Bath waters, so far as the analysis made at The Lancet Laboratory shows, are small quantities of strontium, of lithium, and a trace of bromine. Many mineral waters have for ages been used for curative purposes, and our present knowledge that such waters, while not remarkable in "chemical" composition, are all alike in yielding helium, the product of decay of radium, makes it particularly interesting to examine these waters for radium emanation or niton, as well as for radium itself.

The discovery of the radio-activity of the Bath thermal waters had its origin in the observation that helium is a product of the change of radium. The presence of helium in a water, in fact, implies either that radium is present in the water itself or that the water has been, at one period or another, in contact with radium. The figures subsequently arrived at by Sir William Ramsay are given according to the amount of radium with which the emanation or niton is in equilibrium. The amount of radium in the water of the King's Spring represents only about 1/470th part of a grain in something like 200,000 gallons (0·1387 milligramme per million litres). The niton, however, is present in much greater quantity (1·73 milligramme per million litres). The gas coming from the water contains much more niton than the water itself, so that the water must hold as much as it can at the high temperature at which it emerges (120° F.). The amount of niton in the disengaged gases is that which would be in equilibrium with 33·65 milligrammes of radium in a million litres of water.

Bath, therefore, appears to possess the richest radio-active waters in the country, and it remains to consider what significance this fact possesses in regard to their therapeutic action. There seems to be little doubt, at all events, that whether administered by the skin, as in immersion, or by respiration, as must happen also during the immersion, radio-active energies act directly by improving the processes of nutrition and metabolism. Enzymic activity is promoted and oxidation processes are stimulated to a more complete stage. There is thus produced a higher excretion of urinary solids apart from chlorides, and there is frequently observed a considerable multiplication of red blood cells. In regard to the bactericidal effects of emanation it is interesting to note that the treatment of gonorrhœal arthritis at Bath meets with conspicuous success, which would seem to indicate a destructive action upon gonococci. The opinion, however, of medical men familiar with the hydro-therapeutic practices at Bath is that a definite contra-indication of radium therapy is in tuberculous conditions. Chronic nephritis falls into the same category. The question of contra-indication is clearly decided by what appears to be the main effect of radio-active treatment, which is primarily a stimulation of metabolism. The dosage can be increased at Bath to an almost unlimited extent by supplementing treatment by immersion with the use of vapour sprays for inhalation. A special radium inhalatorium has been installed suitable for this treatment, and the results are most encouraging.

The reputation of Bath has, however, been founded chiefly upon the undoubted benefit which a course of treatment there has conferred upon sufferers from gout in all its forms, chronic articular rheumatism, muscular rheumatism, rheumatoid arthritis, sciatica, and so on. The general experience in these directions teaches that in affording relief to such conditions Bath is in no sense inferior to the spas abroad which have established similar claims.

Amongst other cases which benefit at Bath are certain disorders of the digestive organs, muco-membranous colitis, chronic gastric catarrh, diseases of the skin, anæmia and chlorosis, ailments of women, and tropical infections.

Outside the indications for treatment with the natural thermal and radio-active waters the Bath corporation have provided a remarkably complete installation of auxiliary appliances in the shape of electric hot-air baths, hydro-electric baths, Nauheim treatment, and sulphur and other medicated baths. There are also provided medico-mechanical exercises for joints and muscles on the Zander system. Lastly, the radio-active waters of Bath give excellent results in the treatment of muco-membranous colitis by means of the intestinal or Plombières douche.

The programme of social attractions, recreation, and amusements reflects great credit upon the authorities at Bath, who have established a well-organised and equipped inquiry office where visitors can obtain complete information from day to day as to these important diversions from a course of treatment. There is a magnificent music chamber situated in the building of the Grand Pump Room itself, and the talent provided is of a really high order. The situation of the city is picturesque and attractive, and the shelter afforded by the beautiful hilly country on all sides renders its climate mild and equable. This fact is specially appreciated in the autumn and winter. The architectural beauties of the city's buildings, streets, and squares are well known. The history of Bath as a bathing station of course goes back a long way, and the excavations that have been made in recent years disclosing beautiful Roman designs and construction are of great interest. The remains of the Roman thermæ are quite extensive, and here and there in a well-preserved state, bearing decided evidence of the importance attached to the waters of Bath by the Romans. Coming to later times, the city enjoyed a great vogue amongst distinguished people early in the eighteenth century, but since that date the development of the bathing establishments has proceeded rapidly on scientific lines, which should make Bath a formidable competitor to continental enterprise. Some idea of the extent of the provision demanded for the supply of the radio-active mineral water to the various baths, douches, and sprays may be gained from the fact that in these places there are close upon 1000 taps, while the pipes for the whole service would, if extended continuously, reach a length of no less than 40 miles.

(*To be continued.*)

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on Oct. 29th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College: Philip Heinrich Bahr, M.B. Cantab., L.R.C.P.; Vraspillai Gabriel, L.R.C.P.; Alfred Howell, M.D. Lond., L.R.C.P.; Ernest Rivaz Hunt, M.D. Cantab., L.R.C.P.; Hugh Basil Greaves Newham, L.R.C.P.; and James Herbert Rhodes, M.B. Lond., L.R.C.P.

Licences to practise physic were granted to 67 gentlemen who had passed the requisite examinations.

The following communications were received: 1. From the secretary of the Royal College of Surgeons of England, dated Sept. 24th and Oct. 9th, reporting proceedings of the Council of that College on Sept. 24th and Oct. 8th respectively. The second letter reported that Mr. J. D. M. Cardell had been appointed the twenty-second Jenks scholar. 2. From the Registrar of the General Medical Council, dated Sept. 24th, concerning the maintenance of the minimum medical curriculum during the present national emergency. 3. From Mr. Oswald Sickert, dated Sept. 10th, asking leave to reproduce a photograph of the portrait of Dr. John Arbuthnot in connexion with an illustrated encyclopædia. The request was granted. 4. From Sir R. Douglas Powell presenting to the College a photograph of the painting by Yeames of Harvey at the Battle of Edgehill. The gift was accepted with the thanks of the College.

It was resolved that the President of the College should become, *ex officio*, a member of an Advisory Board to the National Council for Combating Venereal Diseases.

A further report was received from the Censors' Board concerning restrictions in the sale of opium and other narcotics. The Board recommended that Clause 4 of their original report, which clause was referred back to the Board at the quarterly July Comitia, should read as follows:—

> 4. That with regard to prescriptions which, when fully made up, contain 1 per cent. (1 grain in 110 minims, which is approximately 4·5 grains to the fluid ounce) or more of the alkaloids in question, and in the case of every preparation intended for subcutaneous use, the doctor should state in his prescription the number of doses to be supplied. The prescription should not be dispensed more than once unless at each renewal it is fully signed and dated by a qualified medical practitioner.

The report was adopted.

Dr. J. A. Ormerod was re-elected a member of the Committee of Management.

A report, dated Oct. 15th, from the Committee of Management was received and adopted. The report stated that the committee had had under consideration the existing regulation to the admission to the Final Examination of students of colonial, Indian, and foreign universities recognised by the Board. It was considered that the present requirement was a hardship, and the committee recommended that Clause IV. should be altered to read as follows:—

> IV. Members of colonial, Indian, or foreign universities who shall have passed such an examination or examinations at their universities for the degree of Doctor or Bachelor of Medicine or Surgery as shall comprise the subjects of the First and Second Examinations of the Examining Board in England, and who shall have completed the curriculum of medical study required by the Regulations of the Board, will, two years after having passed such examinations, be eligible for admission to the Third or Final Examination of the Board; any candidates so admitted to examination will be required to pay a fee of twenty guineas, and any such candidates who shall have passed the Third or Final Examination shall, on the further payment of not less than twenty guineas, and subject to the by-laws of each College, be entitled to receive the Licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England.

The quarterly report of the College Finance Committee was received and adopted. Amongst other matters it was mentioned that the committee recommended that the College should contribute 200 guineas to the Prince of Wales's Fund for relief of distress caused by the war.

After some further formal business the PRESIDENT dissolved the Comitia.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeon: E. M. W. Hearn to the *Vivid*, additional, for the *Reliance*. Temporary Surgeons: E. M. Thompson to the *Vivid*, additional, for War College, Devonport; J. C. Baggs and H. T. Depree, both to the *Vivid*, additional, for Plymouth Hospital; J. D. Clarke, D. Flack, and K. Wolferstan, all to the *Pembroke*, additional, for disposal; G. C. Scott to the *Wildfire*, additional, for disposal; J. A. Watson, H. Hemsted, and P. W. Carruthers, all to the *Victory*, additional, for Haslar Hospital; and R. N. McKinstry to the *Victory*, additional, for disposal.

ROYAL NAVAL RESERVE.

In accordance with the Regulations for Royal Naval Reserve, Lieutenant William George Lewin has been placed on the retired list (dated Oct. 7th).

The undermentioned Acting Surgeons have been confirmed in the rank of Surgeon in His Majesty's Fleet:—Arthur Edward Panter, Henry Brice Parker, Julian Lionel Priston, Richard Frith Quinton, Mark James Aitken, Joseph Archibald Maxwell, Maurice Sydney Moore, William Glossop Thwaytes, Clarence Edward Greeson, William Forbes Beattie, Herbert Wyndham Fitzroy-Williams, Francis Edmund Fitzmaurice, Timothy Joseph O'Riordan, James Cecil Kelly, James Mulvihill Horan, Gilbert Malise Graham, and Frank Cornwell Hunot.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon: W. J. A. Quine to the *Vivid*, additional, for disposal, vice McDowell.

ARMY MEDICAL SERVICE.

The undermentioned to be temporary Colonels:—Dated Oct. 10th: Lieutenant-Colonel Sir Wilmot P. Herringham, 1st London (City of London) General Hospital, Royal Army Medical Corps, Territorial Force; Sir Almroth E. Wright, F.R.S.; Captain Frederic F. Burghard, 4th London General Hospital, Royal Army Medical Corps, Territorial Force; and Major Sir John Rose Bradford, K.C.M.G., F.R.S., 3rd London General Hospital, Royal Army Medical Corps, Territorial Force.

To be temporary Lieutenant-Colonel:—Dated Oct. 21st: Willie Netterville Barron, M.V.O.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Robert Caldwell is retained on the active list under the provisions of Article 120, Royal Warrant for Pay and Promotion, 1913, and to be Supernumerary (dated Oct. 30th).

The undermentioned Captains to be Majors:—Dated Oct. 31st: John G. Bell, Frederick W. W. Dawson, Joseph E. H. Gatt, Thomas S. Coates, James C. G. Carmichael, Roland H. Bridges, James A. W. Webster, Francis C. Lambert, Reginald C. Wilmot, Harry B. Kelly, Edward M. Pennefather, Benjamin H. V. Dunbar, David Ahern, Donald G. Carmichael, John M. M. Crawford, Thomas E. Harty, John H. Duguid, Burnet G. Patch, and Geoffrey W. G. Hughes.

The undermentioned to be temporary Lieutenants:—Dated Oct. 10th: John Henderson, Lawrence Fielder Hemmans, and William Baxter. Dated Oct. 12th: Tremlett Brewer Batchelor, Noel Anthony Coward, Lionel Palliser Costabadie, John Davidson, Ranald Montague Handfield-Jones, John George Ingouville, Michael John Mulligan, Michael Murphy, George Wardlaw Milne, Humphrey Neame, Vivian Morris Rich, Edward Llewellyn Noott Rhodes, George Thom, John Tichborne, George Wishart Will, and Trevor Owen Williams. Dated Oct. 13th: Adam Gray and William Guy Lidderdale. Dated Oct. 14th: Thomas Renton Elliott. Dated Oct. 15th: Frank Arthur Grange, John Davis Lithgow, James Anstruther Smith, and Malcolm Winfrid Shutte. Dated Oct. 16th: John Westcott Dew. Dated Oct. 17th: John Henry Dyke Acland, Henry Albert Ehrlich, Alexander Fleming, and Robert Charles Irvine.

The undermentioned Cadets and ex-Cadets of the Officers Training Corps to be Lieutenants (on probation):—Dated Oct. 15th: Harold Armstrong Crouch and Francis Augustus Roddy. Dated Oct. 20th: Charles Arthur Mason.

The undermentioned to be Lieutenants (on probation):—Dated Oct. 14th: Donald Charles Scott. Dated Oct. 16th: Wilfrid Burton Wood and Herbert Stewart Milne. Dated Oct. 17th: John Sandys Pooley. Dated Oct. 19th: Quentin Vaughan Brooke Wallace, Gilbert Aberdein Harvey, and William Howard Nicholls.

Charles E. L. Burman relinquishes his temporary commission (dated Oct. 13th).

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers of the Indian Medical Service:—

Colonel to be Surgeon-General:—Dated April 1st, 1912: George Francis Angelo Harris, C.S.I. Lieutenant-Colonel to be Colonel:—Dated April 1st, 1912: Francis James Drury. Lieutenants to be Captains:—Dated Jan. 28th: John Scott and George Selby Brock. Dated April 23rd: Kanwar Indarjit Singh, Krishnan Gopinath Pandalai, and Charles Albert Wood.

The provisional promotions to the rank of Captain of the following officers are confirmed:—William Haywood Hamilton (dated Feb. 1st, 1908), John Francis Boyd (dated Sept. 1st, 1908), and Percy Strickland Mills (dated Feb. 1st, 1909).

CHANNEL ISLANDS MILITIA.

Medical Corps.

Surgeon-Captain Arthur C. Stamberg to be Surgeon-Major (dated Oct. 18th).

TERRITORIAL FORCE.

Army Medical Service.

Major Gerald C. Taylor, from the list of officers, Sanitary Service, Territorial Force, to be Deputy Assistant Director of Medical Services, 2nd Mounted Division, Central Force. Lieutenant-Colonel R. R. Sleman, 1st London (City of London Field Ambulance) Royal Army Medical Corps, Territorial Force, is granted the local rank of Colonel whilst serving at Malta.

Royal Army Medical Corps.

Major James G. McNaught to be Lieutenant-Colonel, vice R. Caldwell, supernumerary. Lieutenant Donald Armour, Royal Army Medical Corps, Special Reserve, to be granted temporarily the honorary rank of Lieutenant-Colonel. William Netterville Barron, M.V.O., to be a temporary Lieutenant-Colonel. Alexander Gordon Paterson is granted temporarily the honorary rank of Major.

1st London General Hospital: The undermentioned Captains to be seconded: William B. Ainger, Herbert D. Clementi-Smith, and George H. L. Whale.

4th London General Hospital: Captain Frederic F. Burghard is seconded.

1st Southern General Hospital: Frank Douglas Marsh (late Cadet, Cambridge University Contingent, Senior Division, Officers Training Corps) to be Captain, whose services will be available on mobilisation.

2nd Northern General Hospital: Major Joseph F. Dobson to be Lieutenant-Colonel.

3rd Northern General Hospital: Captain George H. Pooley to be Major.

1st London (City of London) Field Ambulance: Captain Charles S. Brebner to be Major (temporary).

2nd London (City of London) Field Ambulance: Major William Vernor Sinclair (formerly Royal Army Medical Corps, Special Reserve) to be Major. Ernest Urquhart Bartholomew (late Captain, Special Reserve) to be Major.

3rd London (City of London) Field Ambulance: James Leonard Octavius Tilley to be Lieutenant.

6th London Field Ambulance: Captain John W. Bird (from the Territorial Force Reserve) to be Captain.

5th London Field Ambulance: Major Mowbray Taylor, Retired List, Volunteer Force, to be Major.

1st South Midland Field Ambulance: Henry Philip Thomason to be Lieutenant.

2nd South Midland Field Ambulance: Lieutenant Cyril R. Wallace, from 1st South Midland Field Ambulance, to be Lieutenant.

3rd South Midland Field Ambulance: Lieutenant Charles E. K. Herapath to be Captain.

2nd South Midland Mounted Brigade Field Ambulance: Humphrey Francis Humphreys to be Lieutenant.

1st North Midland Field Ambulance: Captain Henry G. W. Dawson to be Major (temporary). Geoffrey Holmes to be Lieutenant.

1st Lowland Field Ambulance: The undermentioned to be Lieutenants: Arthur William Sutherland, George Balfour Eadie, and Percival John Moir.

2nd Lowland Field Ambulance: Quartermaster and Honorary Lieutenant James Law, from the Lowland Clearing Hospital, to be Quartermaster, with the honorary rank of Lieutenant.

3rd Lowland Field Ambulance: William Wells Greer to be Lieutenant.

Lowland Mounted Brigade Field Ambulance: Andrew Morton Young to be Lieutenant.

2nd West Riding Field Ambulance: Francis William Begg to be Lieutenant.

3rd West Riding Field Ambulance: Donald Sargenson Twigg to be Lieutenant.

3rd Welsh Field Ambulance: William Rutherford and George Young to be Lieutenants.

1st Wessex Field Ambulance: The undermentioned Captains to be Majors: Thomas Duncan and George P. D. Hawker. Lieutenant William H. E. Stewart, from Attached to Units other than Medical Units, to be Captain.

2nd Wessex Field Ambulance: The undermentioned Captains to be Majors: Fielding C. Whitmore and Thomas P. Puddicombe.

3rd Wessex Field Ambulance: Major Alexander Milne-Thomson to be Lieutenant-Colonel. Captain Edmund Alderson to be Major. Charles Balfour Stewart to be Lieutenant.

South Wales Mounted Brigade Field Ambulance: Arthur Malsen Deane (late Lieutenant, 2nd West Riding Brigade, Royal Field Artillery) to be Lieutenant.

1st East Anglian Field Ambulance: Harry Whitaker to be Lieutenant.

3rd East Anglian Field Ambulance: George Hastie Harper-Smith to be Lieutenant.

2nd Highland Field Ambulance: George Spencer Melvin to be Lieutenant.

2nd Home Counties Field Ambulance: James William Cairns to be Lieutenant.

1st West Lancashire Field Ambulance: William Evans Graham to be Lieutenant.

4th (Cumberland and Westmorland) Battalion, The Border Regiment: Lieutenant Norman Maclaren resigns his commission.

1st London (City of London) Sanitary Company: Samuel Reginald Orme Dudfield to be Captain.

2nd London Sanitary Company: Arthur George Atkinson to be Lieutenant.

Sanitary Officers: William McConnel Wanklyn to be Captain.

Sanitary Service: James Albert Gibson to be Captain.

Attached to Units other than Medical Units.—Lieutenant-Colonel and Honorary Surgeon-Colonel Charles H. Gwynn resigns his commission, and is granted permission to retain his rank and wear the prescribed uniform. To be Majors: Captain John Livingstone, Captain Frederick N. Grinling, Captain William F. McAllister-Hewlings, Captain William S. Griffith, and Edward Thomas Vint. To be Captains: Lieutenant Alexander D. Kennedy, Lieutenant Francis V. Denne, Captain George Potts, from the 1st Home Counties Field Ambulance, Harold Christopher Simpson (late Lieutenant 9th (Highlanders) Battalion, The Royal Scots (Lothian Regiment)) Lieutenant James L. Brownridge, and Lieutenant Alexander P. Watson. To be Lieutenants: George Shaw Glass, William Dale (late Lance-Corporal, London University Contingent, Senior Division, Officers Training Corps), Robert Unwin Moffat, C.M.G., Archibald Oliver, William Ernest Fitzgerald, John Ernest Pearce, Stanley Hodgson, Pierce Nagle Creagh, Herbert Edward Murray, Norman Maclaren (late Lieutenant 4th (Cumberland and Westmorland) Battalion, The Border Regiment), Arthur Christopher Watkin (late Second Lieutenant 4th Battalion, The King's (Shropshire Light Infantry)), Stephen Ormond Dolan, Arthur Edwin Bullock, and Frank Rex Fletcher.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Lieutenant Robert Steele Young, from 1st East Lancashire Field Ambulance, to be Lieutenant.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8529 births and 4708 deaths were registered during the week ended Saturday, Oct. 31st. The annual rate of mortality in these towns, which had been 13·9, 13·4, and 13·8 per 1000 in the three preceding weeks, fell in the week under notice to 13·5 per 1000 of their aggregate population, estimated at 18,120,059 persons. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 13·7, against 14·1 per 1000 in the metropolis. Among the several towns the death-rate last week ranged from 4·7 in Hornsey, 5·1 in Exeter, 5·3 in Darlington, 5·7 in Ilford, 6·3 in Cambridge, and 7·3 in Ealing, to 20·4 in Liverpool, 20·5 in Gateshead, 20·8 in Newcastle-on-Tyne, 22·3 in Middlesbrough, and 24·7 in Bury.

The 4708 deaths from all causes were 80 fewer than the number in the previous week, and included 472 which were referred to the principal epidemic diseases, against 529 and 540 in the two preceding weeks. Of these 472 deaths, 204 resulted from infantile diarrhœal diseases, 123 from measles, 61 from diphtheria, 38 from scarlet fever, 32 from whooping-cough, and 14 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·4, against 1·6 per 1000 in the previous week. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had steadily declined from 1223 to 269 in the six preceding weeks, further fell to 204 last week, of which 44 were registered in London, 19 in Liverpool, 14 in Birmingham, 11 in Manchester, 10 in Newcastle-on-Tyne, 8 in Stoke-on-Trent, and 8 in Sheffield. The deaths referred to measles, which had been 73, 67, and 101 in the three preceding weeks, further rose to 123, and caused the highest annual death-rate of 1·7 in Wigan and in Newcastle-on-Tyne, 1·8 in Liverpool, 2·0 in Wakefield, and 2·3 in Birkenhead. The fatal cases of diphtheria, which had been 57, 59, and 79 in the three preceding weeks, fell to 61 last week, and included 20 in London, 6 in Birmingham, 4 in Manchester, 3 in Liverpool, and 2 each in Leyton, Northampton, and Great Yarmouth. The deaths attributed to scarlet fever, which had been 31, 29, and 37 in the three preceding weeks, were 38 last week, of which 10 occurred in London, 7 in Manchester, 4 in Liverpool, and 2 each in Birmingham, Preston, and Leeds. The deaths referred to whooping-cough, which had declined from 50 to 35 in the four preceding weeks, further fell to 32 last week, and included 6 in London, 4 in Liverpool, and 2 in Nottingham. The fatal cases of enteric fever, which had been 17, 14, and 19 in the three preceding weeks, fell to 14 last week, of which 4 occurred in London and 4 in Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 4617 in the ten preceding weeks, had further risen to 4683 on Saturday last; 598 new cases were admitted during the week, against 670, 650, and 657 in the three preceding weeks. These hospitals also contained on Saturday last 1505 cases of diphtheria, 69 of enteric fever, 54 of whooping-cough, and 47 of measles, but not one of small-pox. The 1224 deaths from all causes in London were 49 fewer than in the previous week, and corresponded to an annual death-rate of 14·1 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 110 to 191 in the six preceding weeks, further rose to 197 in the week under notice, and were 19 in excess of the number registered in the corresponding week of last year.

Of the 4708 deaths from all causes in the 97 towns, 215 resulted from different forms of violence and 367 were the subject of coroners' inquests, while 1409 occurred in public institutions. The causes of 29, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 77 other smaller towns. Of the uncertified causes of death, 9 were registered in Birmingham, 6 in Liverpool, and 4 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1127 births and 640 deaths were registered during the week ended Saturday, Oct. 31st. The annual rate of mortality in these towns, which had been 15·9, 14·7, and 15·0 per 1000 in the three preceding weeks, declined to 14·6 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 15·1, against 13·7 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 6·8 in Hamilton, 7·6 in Motherwell and in Kirkcaldy, and 10·1 in Dundee, to 15·0 in Leith, 15·7 in Aberdeen, and 16·5 in Glasgow.

The 640 deaths from all causes were 19 fewer than the number in the previous week, and included 78 which were referred to the principal epidemic diseases, against numbers declining from 96 to 80 in the three preceding weeks. Of these 78 deaths, 26 resulted from infantile diarrhœal diseases, 16 from diphtheria, 14 each from scarlet fever and whooping-cough, 5 from enteric fever, and 3 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against 1·4 per 1000 in the 97 large English towns. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 54, 29, and 31 in the three preceding weeks, fell to 26 last week, of which 14 were registered in Glasgow, 5 in Aberdeen, and 2 in Edinburgh. The deaths referred to diphtheria, which had increased from 4 to 19 in the six preceding weeks, fell to 16 last week, and included 6 in Edinburgh, 4 in Glasgow, and 3 in Aberdeen. The fatal cases of scarlet fever, which had increased from 6 to 16 in the six preceding weeks, fell to 14 last week; 7 deaths occurred in Glasgow, 3 in Aberdeen, and 2 in Leith. The deaths attributed to whooping-cough, which had been 8, 10, and 9 in the three preceding weeks, rose to 14 last week, of which 9 were recorded in Glasgow and 2 in Paisley. The 5 deaths referred to enteric fever, of which 3 occurred in Glasgow, were equal to the average in the three preceding weeks. Of the 3 fatal cases of measles 2 were recorded in Glasgow and 1 in Dundee.

The deaths referred to diseases of the respiratory system, which had steadily increased from 62 to 89 in the six preceding weeks, further rose to 92 in the week under notice; 17 deaths resulted from various forms of violence, against 29 and 21 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 592 births and 352 deaths were registered during the week ended Saturday, Oct. 31st. The annual rate of mortality in these towns, which had been 15·4, 16·2, and 15·8 per 1000 in the three preceding weeks, fell to 15·2 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 15·7, against corresponding rates of 13·7 and 15·1 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 14·4 in Dublin (against 14·1 in London and 16·5 in Glasgow), 14·0 in Belfast, 21·8 in Cork, 11·4 in Londonderry, 21·7 in Limerick, and 22·8 in Waterford, while in the 21 smaller towns the mean death-rate was 15·4 per 1000.

The 352 deaths from all causes were 13 fewer than the number in the previous week, and included 51 which were referred to the principal epidemic diseases, against 57 and 44 in the two preceding weeks. Of these 51 deaths, 19 resulted from infantile diarrhœal diseases, 12 from scarlet fever, 7 from measles, 5 from diphtheria, and 4 each from enteric fever and whooping-cough, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·2, against 1·4 and 1·8 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had steadily declined from 74 to 21 in the six preceding week, further fell to 19 last week, of which 7 were registered in Dublin, 6 in Belfast, and 2 in Cork. The deaths referred to scarlet fever, which had been 4, 7, and 5 in the three preceding weeks, rose to 12 last week, and comprised 4 in Waterford, 3 each in Belfast and Limerick, and 2 in Dublin. The 7 fatal cases of measles, comprising 6 in Belfast and 1 in Dublin, were equal to the number in each of the two preceding weeks. Of the 5 deaths attributed to diphtheria, 2 occurred in Kilkenny. The 4 deaths referred to whooping-cough were 2 below the average in the three preceding weeks, and included 3 in Cork and 1 in Belfast. Of the 4 fatal cases of enteric fever, 2 occurred in Dublin, and 1 each in Belfast and Ballymena.

The deaths referred to diseases of the respiratory system, which had been 56, 71, and 60 in the three preceding weeks, were 61 in the week under notice. Of the 352 deaths from all causes, 122, or 35 per cent., occurred in public institutions, and 6 resulted from different forms of violence. The causes of 15, or 4·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes last week did not exceed 0·6 per cent.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: NEW CALENDAR.—A new edition of the Calendar of the Royal College of Surgeons of England has just been published. The Calendar contains a full statement of the number of candidates who were admitted to examination during the collegiate year to the Fellowship, to the first, second, and third examinations, and to the examination for the Licence in Dental Surgery respectively, together with the results of the several examinations. The Fellows of the College number 1641, the oldest of whom are Mr. Richard Barwell and Mr. Thomas Bryant, who both qualified as Fellows on May 12th, 1853. The Members' list contains 17,161 names, and the Licentiates in Dental Surgery 2635. Particulars of the various College prizes are included in the Calendar, and for the first time details are given of the Blicke Bequest "for the purchase of books for the library for ever." The first award of the Sir Gilbert Blane Medal under the revised regulations was made during the year to "the medical officer who obtained the highest aggregate marks at the examination to the rank of staff surgeon." The Calendar states that a clock for the Common Room for Fellows and Members has been presented by Mrs. M. F. King in memory of her father, the late Mr. W. C. B. Fifield, M.R.C.S., of Boston, U.S.A. It is to be noted that Mr. Frederic G. Hallett, the secretary to the Examining Board, has been given the title of Director of Examinations.

PARIS.

(From our own Correspondent.[1])

The Unforeseeable.

All the preparations of the French Medical Service with regard to the organisation of ambulance work and attendance on the wounded have been upset by the unforeseeable methods of the enemy in systematically firing on the ambulances, killing medical officers and nurses, and abandoning the wounded on the field of battle. It has accordingly been necessary to modify all our arrangements, which had been planned with a view to more modern and humane methods in warfare. Dressing stations near the firing line, collecting stations, ambulances, field hospitals, admirably organised transport for the wounded, the material of various sanitary stations provided abundantly with serums and radiographic apparatus—all might have been considered perfectly organised. But under the methods of our foes it became no longer possible to attempt to succour the wounded and, after furnishing first aid, to remove them promptly out of the battle area. A horrible condition of affairs has resulted because the entire equipment was provided for a different and more humane method of warfare. The hospital trains, so admirably equipped, in which the wounded, comfortably settled and attended by an adequate ministering personnel, would have been transported from the collecting stations to the field hospitals, have but rarely been able to render the aid one had a right to expect from them, because of the impossibility of finding them when needed in the vicinity of the fighting line with a number of conveyances adequate to the number of wounded to be removed at one time. Consequently, trains returning empty from revictualling the troops, which with admirable organisation proceed daily to the neighbourhood of the field of battle, have had to be made use of. The wounded, dressed at the field ambulances, have been piled into these trains, and it is on the échelon of railway dressing stations in the line of communications that the task has devolved of readjusting the dressings, and in the case of the wounded unable to continue the journey of diverting them to the field hospitals, there to complete the work which could only be hastily done by the ambulance. These field hospitals are always exposed to the necessity of advancing or retiring in accordance with the movements of an enemy to whose tender mercies it is highly imprudent to abandon the wounded. Naturally these railway dressing stations, intended only for a stay of a few moments by the hospital trains provided with every requisite, have had to perform a herculean task under very inadequate conditions. Little by little the personnel and material of these stations have been adapted to the new situation. The supply trains, in view of conversion on their return into extemporised hospital trains, have carried with them the personnel and material of the Medical Service. The railway dressing stations have been enlarged and provided with more complete and comfortable equipment. Now great progress has been made. The use of straw for the wounded to lie on has been long forbidden. They are placed on stretchers when they cannot sit in the railway carriages; they are provided with sufficient covering, and a hospital attendant stays in each wagon. Moreover, all the railway companies are devoting their attention to this matter. The Compagnie de l'Est has recently established a hospital train supplied with heat in all the carriages and having a communicating corridor, gas lighting, a dressing-room, water closets and lavatories, and placed on bogies. This train has been presented to a committee composed of the highest medical authorities, and others are being established.

Tincture of Iodine and the Army.

The bullet when it finds its mark is aseptic, and when it strikes direct creates a wound like that of a surgical knife, but this wound becomes invaded with great rapidity by pathogenic microbes, either from the earth or from the skin itself. The skin of soldiers who frequently are fighting for days and nights together without taking off their clothes is naturally dirty and septic. From the skin these microbes enter the wound and infect it deeply in a few hours. Swabbing the infected skin with tincture of iodine suffices to secure asepsis, but that is not the case with a wound when the microbes have colonised in it; then swabbing with iodine is powerless. But bullet wounds painted with tincture of iodine immediately after their infliction and before the application of the first dressing follow an aseptic course. It is therefore necessary that the swabbing with iodine should be immediate, and this is possible only if the soldiers themselves have the necessary material at their disposition—a difficult matter to ensure. Fortunately, this difficulty has now been solved by the manufacture of friable ampoules of tincture of iodine, made of hermetically sealed glass. Their diameter is 6 mm., their length from 6 to 7 mm. Near one end they are contracted, and the bottom of the neck which divides them into two unequal bulbs separated by a file mark. The larger bulb is held between the right forefinger and thumb, the smaller being in the left hand. A slight pressure suffices to break the ampoule between the two bulbs. The large bulb contains a soft cotton brush with which it is very easy to paint a much larger surface than that of a single dressing. Each ampoule is enclosed in a small cardboard box strong enough to protect it. The whole apparatus is not much larger than a small pencil. Professor Pierre Delbet has expressed his strong approbation of it. Thanks to private generosity, 6000 ampoules were at once sent to the firing line, and each day during the past week a similar number has been despatched and the supply will be kept up. The net cost is very slight, and it is hoped that all our soldiers will be provided with them.

Nov. 1st.

Danger of Small-pox in Dublin.—Sir Charles Cameron, superintendent medical officer of health of Dublin, has addressed a letter to the press directing attention to the large number of young persons in Dublin who are unvaccinated. For some years past the boards of guardians in the neighbourhood of Dublin and some other districts have been neglectful of their duty as to the administration of the vaccination laws, and the Local Government Board has contented itself with the occasional expression of a pious opinion on the subject. With a large number of foreign refugees arriving in Dublin the danger of the introduction of small-pox is greatly increased, and were a few cases to occur an epidemic could hardly be avoided.

MEDICAL RECORDS OF THE WAR.

To the Editor of THE LANCET.

SIR,—It is noteworthy that we possess no complete medical history of any of the numerous wars in which the British army has been engaged during the last century. If, for example, any one of us desires to inquire into the mortality from zymotic disease during the Crimean or even during the more recent Boer war, there is no easily accessible authoritative survey of the medical proceedings of either war to which we naturally turn for the required information. After much search we might, it is true, come across it in some excellent article contributed to the *Journal of the R.A.M.C.*, but, again, we might not, or we might hunt it down in the Annual Reports of the Director-General. But despite the abundant time and efforts which they represent Blue-books and other official documents are not literature. As likely as not the library we are accustomed to use does not stack these on its shelves. This is a defect which should be remedied in the greatest and gravest war with which our country has ever been overtaken, a war in which, taking into account the relatively small size of our army, success will very largely depend upon the reduction of preventable disease to a minimum among our troops and upon the preservation of the greatest possible number of our men in a state of health and strength upon the battle line, in which, therefore, the Royal Army Medical Corps will be a foremost factor.

But if such a history is to be written it must (1) be official; and (2) it must be based upon precise data. That is to say, from the beginning it must be clearly borne in mind by the whole medical staff that the data bearing upon each case must be so collected and recorded as to be serviceable for future reference. In the matter of case reports and records the Royal Army Medical Corps has a system that is beyond reproach. It must be remembered, however, that there are many voluntary agencies at work, hospitals equipped and manned by those hitherto unconnected with the army organisation. If any one unit fails to do its duty it renders the whole record imperfect. It is essential, therefore, that a small and authoritative body be appointed that, under the control of the Director-General, shall have oversight, collection, and preservation of hospital and other medical records. The active members of the Royal Army Medical Corps are rightly occupied in meeting the vital needs of the moment; it would be unwise to demand that certain of their number be called off to take special charge of this work. It is doubtless this very devotion of a well-worked body to immediate needs that explains the non-existence of authoritative medical histories of previous wars. The work could be accomplished equally well by medical men of standing and authority outside the service, once they had familiarised themselves with the statistical methods of the Director-General and his staff. Not mere clerks are wanted, but men possessing such status that their directions would be accepted and fulfilled by the different hospital units. There can be no lack of medical men of high standing above the military age of service who would gladly, not to say eagerly, embrace such opportunity to be of service.

Those of us who are associated with hospitals know well that there is no greater stimulus to thoroughness and efficiency on the part of the medical staff, from the highest to the lowest, than is afforded by a good system of case reporting and record. A case well reported is a case well studied; and careful diagnosis and right treatment are the natural sequence. Wholly apart from the matter of future utility, a committee charged particularly with the oversight of the medical records of the war would contribute materially to the efficiency of the medical service and the welfare of our troops.

I am, Sir, yours faithfully,

J. GEORGE ADAMI.

McGill University, Montreal, Oct. 20th, 1914.

THE WOUNDED IN THE WAR.

To the Editor of THE LANCET.

SIR,—May I venture to confirm the opinion expressed elsewhere that the care of our wounded needs immediate supplementation, not by the appointment of a few consultant diagnosticians, but in notably increasing the staffs and equipment of the base hospitals in France by sending out a number of hospital surgeons of experience? The condition in which the wounded arrive here, the statements they make of the want of surgical attention during transport, especially in trains, the fact that many cases are prejudiced (some have even died) by being put on board ship when they should have been treated at a base hospital, are all clearly due to a shortage of experienced surgeons on the other side of the Channel.

There are a number of Territorial medical officers like myself who found ourselves practically unemployed by the War Department as soon as we had completed the preparation of the base hospitals. In thereupon volunteering, as I did on August 12th, to be transferred to the Active Service List, I addressed on August 16th a memorandum to the Director-General venturing to suggest that as under the circumstances of the present war sudden pressure on the bases must be expected, the appointment of consultants as in the Boer war would not be so useful as the addition of a number of us to the Expeditionary Force as supernumerary surgeons of hospital experience who could be sent by the principal medical officer to serve base hospitals wherever the pressure was greatest. This suggestion, however, has not so far been accepted, and though naturally one is in favour of one's own view, I cannot help still feeling that our wounded are not receiving all the surgical help their splendid services deserve.

I am, Sir, yours faithfully,

Nov. 2nd, 1914. VICTOR HORSLEY.

VOLUNTEER SURGEONS FOR FRENCH HOSPITALS.

To the Editor of THE LANCET.

SIR,—You were kind enough to publish on Sept. 26th a letter of mine written at Crépy-en-Valois, in which, amongst other matters, I made an appeal for surgeons for the French hospitals near the front. To that letter I am glad to say I had the large number of 153 replies, many of them from men holding important positions in London and provincial hospitals as surgeons or anæsthetists.

My letter was copied or extracted in some French journals, with the unlooked-for result that I have become an unofficial agent for French hospitals seeking British surgeons and for British surgeons willing to give their services for periods varying from one to two or in some rare cases for three months.

I forwarded my earlier lists to the British Red Cross Society. Lord Kitchener took some of the younger men for the Royal Army Medical Corps, while the society took some others who were willing to "sign on" for at least six months. This was, of course, for the service of our own troops. I wish not to be thought as in any way criticising the splendid work done by this organisation as regards the object for which it was primarily instituted, and it is satisfactory to be able to state that, as far as I have had opportunities of judging, everything possible, even in very difficult circumstances, has been done for our wounded or sick soldiers.

During the last few weeks I have been several times asked to find French-speaking volunteer surgeons who would work for short periods under the Croix Rouge Française. The French committees who ask for this assistance are in this position: They are in large towns having in normal times a well-trained body of hospital and private practitioners. At present nearly all their operating surgeons are at the front or in the clearing hospitals close to it. The local committees are doing the general work of these large auxiliary hospitals with the help of the general practitioners in the town. In a great many cases they would be glad of the services of one or two experienced British surgeons who have some facility in French. They know they cannot afford to pay anything like a suitable fee for such services for a long period, and, to put it quite plainly, they do not want young men just qualified who may not command the confidence of the local practitioners. What they do want are men of good surgical experience who would be willing to give their services for, say, six weeks or two months at a time. They would be expected to perform such operations as were required in fresh cases, or as became necessary in the course of treatment. Also to help the local men with advice when called on and, in fact, to act as consulting and operating surgeons.

Last week I was asked somewhat urgently for two surgeons for a large town in central France where a new hospital with 300 beds is being opened in addition to some hundreds already provided. As I had no more French speakers on my list I wrote to the British Red Cross Society. I had a reply that my letter had been handed to their Anglo-French Committee, who would consider it on receiving further particulars.

The difficulties of this committee are that to a certain extent their action must be general and dictated by the policy of some central organisation, whereas what is wanted is far more flexibility which would allow of the kind of man suitable for the purpose proceeding at once to the place where it is known that his services are needed. Hitherto the policy has been to send a "unit" consisting of a surgeon and nurses who take complete control of the hospital provided by the French organisation with exclusion of the local medical men and nurses, on the plea that French surgery and nursing are not on English lines or up to our standard. I have just been informed that the committee are now willing to coöperate in sending voluntary surgeons on the lines indicated above as soon as the present strain on their organisation has slackened.

I have been requested to continue my work as an intermediary for obtaining surgical assistance in French towns on the grounds that a change in its management would cause inconvenience to many persons in France who may write to me in the present slow course of post. I shall be glad to hear from any French-speaking surgeons willing to give their services on the above lines. I am working now in connexion with the London committee of the Croix Rouge Française, through whom the necessary arrangements as to fares, &c., will be made. At the present moment I have inquiries for two more surgeons.

I am, Sir, yours faithfully,
JAMES DONELAN.

6, Manchester-square, London, W., Nov. 2nd, 1914.

PROGNOSIS IN CANCER OF THE TONGUE.

To the Editor of THE LANCET.

SIR,—In his very interesting article upon "Prognosis in Cancer of the Tongue" in THE LANCET of Oct. 24th Mr. W. Trotter states that the chief post-operative dangers are those of infection of the lungs and infection of the wound. Of the latter I am not competent to speak; the former come within my province, for they are due in all cases to the aspiration of septic material during anæsthesia. The choice of the method of administration therefore assumes much importance, and it is in this connexion that I venture to make some suggestions and some criticisms of Mr. Trotter's remarks.

Of the two methods of administration mentioned —viz., a preliminary tracheotomy or laryngotomy and plugging of the pharynx, and the intratracheal insufflation of ether—Mr. Trotter employs the first and is hostile to the second. His reason is that he thinks there is a "risk of conveying septic material into the trachea during the introduction of the tube." He does not say that this has happened, nor do I know whether his fears are justified, but it is conceivable that if the catheter (tube) is introduced by the *indirect* method it might happen. By means of *direct* laryngoscopy, however, the catheter is inserted absolutely sterile without coming into contact with anything but the interior of the laryngoscope. For this and for other reasons I have always advocated the direct method, and Mr. Trotter's remark supports my opinion. I believe moreover that not only in this country but in the United States anæsthetists almost universally use this method, and that those who started their intratracheal novitiate by using the indirect method have later abandoned it with increasing experience of its difficulties and uncertainties. Direct laryngoscopy may not appear easy at first, but it is soon mastered, and is then quite certain and without danger.

Our experience at Guy's is very decidedly in favour of intratracheal insufflation, and I do not think I exaggerate when I say that for nearly two years now no other method has been used in these mouth cases when it has been possible to obtain the services of an anæsthetist acquainted with the technique. My own experience in this particular class of operation is based upon nearly 100 cases, 48 of these having been for malignant disease in patients usually, of course, of an advanced age. No pneumonia has occurred; the anæsthesia has always been entirely successful. My impression is that surgeons will not continue to use any method which has only a "paper reputation" to back it. Meltzer's method has made good its claims in these cases.

Infection of the lungs occurs "not very uncommonly" after a preliminary gland operation, due, as Mr. Trotter points out, to an obstructed airway and vigorous breathing leading to aspiration from the mouth. To prevent this risk Mr. Trotter has apparently to choose one of two alternatives, either to do the gland and mouth operations in one stage or to do a preliminary laryngotomy or tracheotomy at both stages. I do not think the latter is at all likely; the former is not always advisable. Some patients therefore must run the risk of pneumonia, unless suitable precautions can be taken. This is exactly where intratracheal administration is so valuable. An excellent anæsthesia is obtained and infection of the lungs does not occur.

May I in conclusion say that tracheotomy is not always so "quickly done" that it does not add appreciably to the length of anæsthesia, a serious thing in many elderly patients about to undergo an extensive operation? Whether it is as harmless as the introduction of a catheter through the larynx is hardly open to question.

I am, Sir, yours faithfully,
FRANCIS E. SHIPWAY.

Queen Anne-street, W., Oct. 29th, 1914.

SIR JAMES Y. SIMPSON AND ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In your issue of to-day Sir William Osler, by his interesting extract from Sir J. Y. Simpson's letter to Dr. Bigelow, shows that Simpson repudiated the suggestion that he had used chloroform as an anæsthetic before ether. Indeed, he could not have done otherwise, for it is on record that he used ether for the first time in midwifery practice on Jan. 19th, 1847, whereas it was not until Nov. 4th of the same year that he introduced chloroform as an anæsthetic to his friends J. M. Duncan and Keith. A graphic account of this celebrated symposium in the "Athens of the North," when chloroform was the fare and not a Chian vintage, has been given by Professor Miller.[1] It is, however, on the question of priority in the use of ether that I venture to address you.

Simpson, according to the extract from his letter quoted by Sir William Osler, after discussing the rival claims of Jackson, Wells, and Morton, decided in favour of Morton. He therefore does not seem to have known in 1870 that Dr. Crawford W. Long, of Athens, Georgia, undoubtedly used sulphuric ether as an anæsthetic during minor operations four years and six months before it was so employed by Morton at the suggestion of Jackson, and nearly three years before Wells used it at Marcy's suggestion, and discarded it in favour of nitrous oxide. Long's first anæsthesia with sulphuric ether was on March 30th, 1842. Morton's first anæsthesia with sulphuric ether was on Sept. 30th, 1846. Wells's first anæsthesia with nitrous oxide gas was on Dec. 11th, 1844. A few days later he experimented on himself with sulphuric ether, but resolved to adhere to nitrous oxide alone. Dr. Marcy, of Martford, in January, 1845, gave the vapour of sulphuric ether to a sailor for the extirpation of a small wen on the side of his head. "The patient was insensible and the operation successful, but Marcy after this experiment still advised Wells to stick to the gas as being more agreeable and perhaps safer than ether."

For the evidence on the whole matter reference may be made to a paper by Dr. J. Marion Sims, New York, in the *Virginia Medical Monthly*, May, 1877, a reprint of which is in the library of the Royal Society of Medicine. It is fair to mention that the discovery of sulphuric either as an anæsthetic by Marcy, Jackson, and Morton was made without knowledge of Long's work. Long's fame was confined to the circle of a small country town. He waited for the opportunity—which never came—of performing some major operation under ether before communicating his experiences to the scientific world. It was not until 1853, when Morton and the friends of Wells and Jackson were clamouring for State recognition and reward for their labours, that Crawford W. Long made good his claim to priority in bestowing the gift which has since become "the blessed possession of the whole world."

I am, Sir, yours faithfully,
LEONARD GUTHRIE.

Upper Berkeley-street, W., Oct. 31st, 1914.

APPENDICITIS IN CHINA.

To the Editor of THE LANCET.

SIR,—I have read with great interest the article in THE LANCET of July 25th last, entitled "The Geographical Distribution of Appendicitis." I would like to say that the experience of those gentlemen who have practised in China mentioned in this paper does not coincide with mine. I am in charge of a hospital with an out-patient department of 100 patients daily, and in four years I have seen two undoubted cases of appendicitis. Both cases refused operation. One died subsequently, the second recovered.

A third case was that of my chief assistant, Dr. H. H. Wang, who had appendicitis. I removed a gangrenous appendix within the first 48 hours. This gentleman, who has been attached to the hospital for 20 years, expresses the opinion that appendicitis is exceedingly common among the Chinese. Cases which he recalls now as simply peritonitis he regards as having an appendicular origin.

Moreover, I do not agree that the Chinese food and habit do not favour appendicitis. Constipation is common, and while it is true that rice is eaten in a beautifully cooked condition, at the same time raw cucumbers, raw marrows, &c., are consumed among the coolie classes who form the bulk of the nation.

I am, Sir, yours faithfully,
HUGH B. KENT,
Medical Officer, Kailan Mining Administration.

Tongshan, North China, Sept. 26th, 1914.

THE WAR AND MEDICAL STUDIES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 31st there is an annotation on the above subject, in which it is said that the shortage of medical students is alarming with reference to the future supply of medical men. I should like to point out that although this shortage may be due to some extent to the war it is very largely due to the National Insurance Act, and began long before the war broke out. Under existing circumstances a young medical man without capital must either do panel work or starve, as he cannot now settle in a working-class neighbourhood and acquire a private practice comparatively quickly. I have met many medical men who have told me that they had intended their sons for the medical profession before the Act was passed, but have now put them into some other calling. The large majority of existing medical men have been forced to take panel work or lose a large proportion of their practices, but many of these have decided that it would be cruel to put their sons into a profession in which a large portion of the work obtainable is done under the degrading conditions of the Insurance Act. I am not a politician, and I regard both parties in Parliament as equally responsible for the degrading condition of medical men under the Insurance Act, but I do not see why the war should be blamed for that for which it is not responsible.

---

[1] Surgical Experiences of Chloroform, 1848-49

I am, Sir, yours faithfully,
LESLIE THORNE THORNE, M.D.Durh.
Harley-street, W., Nov. 2nd, 1914.

To the Editor of THE LANCET.

SIR,—With regard to your annotation on the War and Medical Studies in THE LANCET of Oct. 31st, I should like to draw your attention to one aspect of the question omitted by you. In most of the teaching hospitals of London, and I have no doubt in the provinces, many students belonging to the Royal Army Medical Corps branch of the Officers Training Corps joined the forces as orderlies in the Royal Army Medical Corps and are now attached to the various military hospitals. Several, if not all, of these have passed their second university examination in medicine or its equivalent in the colleges, and the authorities are allowing the time spent in the wards of these hospitals to count in their curriculum. I trust, however, that facilities will be given them on the expiration of their six months to attend other hospitals and classes so as to qualify as quickly as possible, since they will be extremely useful as qualified men should the war continue after this period. I am, Sir, yours faithfully,

R. KING BROWN, M.D. R.U.I.
Bermondsey, S.E., Nov. 2nd, 1914.

OSTEO-ARTHRITIS OF THE HIP-JOINT.

To the Editor of THE LANCET.

SIR,—In a letter in THE LANCET of Oct. 10th Mr. W. J. Midelton has done us the honour of referring to a contribution by ourselves on "Osteo-arthritis of the Hip and its Diagnosis in Early or Pre-osteophytic Stages." While grateful to Mr. Midelton for his strictures we must confess that they appear to us both carping and irrelevant. In commenting on our paper he states: "I have long held that wherever there is neuritis there is always arthritis." With regard to this sweeping assertion we venture to affirm that there is nothing in our contribution to justify such an inference being drawn, and his experience must be wholly diverse from our own, and indeed for that matter from all other students of osteo-arthritis as evidenced by their writings.

The nerve pains in osteo-arthritis are referred and *neuralgic* in nature, and a genuine *neuritis*, whether of the sciatic or anterior crural trunks, is exceptionally rare. Adams in his classical treatise cites only one instance, that of the late Dr. Perceval, of Dublin. This great physician was afflicted with well-marked malum coxæ senilis and suffered severely from pain along the path of the anterior crural nerve. At necropsy it was found that this trunk was inflamed owing to its being stretched over an osseous deposit springing from the front of the right acetabulum. In rare instances, too, a similar neuritis has been produced in the sciatic trunk by exostoses projecting from the posterior rim of the cotyloid cavity, and such outgrowths in isolated cases have been removed with resulting amelioration of the neuritis. Space forbids our dwelling on the many other instances at variance with Mr. Midelton's assertion that wherever there is neuritis there is always arthritis.

We have still greater difficulty in accepting the further assertion made by him that "in osteo-arthritis the actual germs are present in the joint." Certainly, as far as we are aware, Mr. Midelton's experience on this point is unique. The only concession we feel inclined to admit here is that changes indistinguishable from osteo-arthritis sometimes supervene secondarily in joints the seat of old tuberculous, gonorrhœal, or other types of infective arthritis. But the development of such changes we would suggest is susceptible of another etiological explanation. The cases that develop these secondary osteo-arthritic changes are those types of infective arthritis in which grave disorganisation of the articular ends has occurred. As a result thereof the joint surfaces lose their normal coaptation, and a state of incongruence on the part of the articular surfaces is established. It follows, therefore, especially in the joints of the lower limb, that the static efficiency of the articulation is impaired and the lines of transmission of body weight are altered. In this way often parts of the joint surface not normally in contact become so, and *vice versâ* those usually in apposition lose touch with each other. A joint placed at such a mechanical disadvantage is obviously subjected to a series of more or less continuous slight strains or injuries. Thus, for example, in the hip the capsule undergoes torsion and the ligamentum teres which transmits the nutrient artery becomes twisted with possible interference of the blood-supply, and in this way there follows in sequence to mechanical instability a state of disorganised or deficient nutrition which in long years is evidenced by erosion and the bony outgrowths typical of osteo-arthritis. One has but to study closely specimens of this disease to note how the very location of exostoses betrays an effort on the part of nature to counteract the instability of the disabled articulation. It is impossible to dwell at length on the importance of static and mechanical agencies as etiological factors in osteo-arthritis, but the view certainly derives great support from the fact that external traumata as opposed to the internal traumatisms we are now considering play a leading rôle in the etiology of osteo-arthritis.

In accordance with his view as to the infective origin of this disease, Mr. Midelton cavils at what he terms the meagreness of our notes on treatment, laying especial emphasis on the absence of any suggestions on our part for combating the germs he believes to be responsible for the origin of osteo-arthritis. This to our mind is somewhat unfair, as the title of our paper distinctly indicates that it is devoted to the question of early diagnosis, and naturally in conformity therewith such remarks as we made were simply incidental. At the same time in justification we may draw his attention to the fact that, granting our conception of the etiology of the disease to be correct—namely, that it is due to traumata of external or internal origin—the principles of treatment were clearly laid down. As to his own method of combating the germs, Mr. Midelton enters into no detail, and we would be much obliged if he would indicate the particular type of organism or organisms which in his view are invariably to be found in the joint cavities.

Lastly, as to Mr. Midelton's view that blistering is of great value in "early and late cases of osteo-arthritis in remedying to some extent the changes in the cord and checking the ravages of germs." On this point we admit that counter-irritation is of great value in alleviating the local and referred pains of osteo-arthritis; but in our experience direct local vesication over the affected nerve trunks is all that is necessary, and we have never found it needful to advise the prolonged blistering of the cervical and lumbar enlargements of the spinal cord as advocated originally by Dr. Latham. Neither, if we may say so, does Dr. Latham himself advocate this treatment in *osteo-arthritis*, for as far as we have understood his writings he restricts this form of treatment to *rheumatoid* or *atrophic* arthritis, a disorder, in our opinion, absolutely distinct from hypertrophic or osteo-arthritis. Mr. Midelton demurs at the absence of any allusion on our part to the changes which he affirms occur in the cord in osteo-arthritis. As far as we are aware no changes have been established in the cord in osteo-arthritis, and there is grave reason to doubt whether the cord changes in the allied condition, rheumatoid arthritis, meagre as they are, are of the nature of causal lesions.

In conclusion, rightly or wrongly, the impression made upon us by Mr. Midelton's letter is that through some misunderstanding he has misconstrued our contribution as referring to rheumatoid and not to osteo-arthritis, though we had supposed our article was sufficiently lucid to dispose of any doubt as to the exact nature of the arthritis we set out to deal with.

We are, Sir, yours faithfully,
A. BASSETT JONES.
Aberystwyth, Nov. 1st, 1914. LL. JONES LLEWELLYN.

TRAUMATIC TETANUS.

To the Editor of THE LANCET.

SIR,—I should be glad if you would kindly allow me to correct a misprint in my paper on the above subject in your issue of Oct. 31st. Referring to the relative potency of tetanus toxin (p. 1038) the computed fatal dose of which for a man of 75 kilogrammes is 0·23 milligramme, the next sentence at present reads, "As the computed dose of dried cholera venom is 4·38 milligrammes." The word "cholera" is a misprint for *cobra*.

I am, Sir, yours faithfully,
London, W.C., Nov. 2nd, 1914. M. H. GORDON.

THE WAR AND THE DISLOCATION OF PRIVATE PRACTICE.

To the Editor of THE LANCET.

SIR,—Some weeks ago when you first commented upon this dislocation in your columns I ventured to write to you on the subject, but you then doubtless for sufficient reasons apparently ignored the contents of my letter. As you have again adverted to the subject I venture to address a second communication to you, more especially as you appear in your issue of Oct. 24th to attempt to saddle the responsibility on the wrong horse. The War Office, i.e., Lord Kitchener, as long ago as August 14th in a circular letter wrote as follows:—"(W.O. Circular letter 9/Gen. No. (T.F.I.)/4087). Lord Kitchener is fully aware that the spirit of the Territorials would induce many to volunteer for foreign service, although they may have very important duties to look after in this country which necessitate their remaining at home. He would point out that home defence is a very important matter, and he does not desire that those who cannot on account of their affairs volunteer for foreign service should by any means be induced to do so, or on account of any such inability should leave the Territorial Force." And in another paragraph of the same letter he states that he hopes to be able to arrange that the training of the Territorial Force (Home Defence) may be on a system by which leave can be given for those serving to look after their urgent private affairs, somewhat on the 'commando' principle which prevailed in South Africa. Now these views seem to have been more or less embodied in Army Order 9/IX/Reserve/1436, Section 3, subsection (*a*) of Oct. 17th, wherein it is stated that where certain members of the Territorial Force require to be released from military duty, the Army Council will give authority for such release on its being satisfied that in every individual case the officer is urgently required in the public interest for employment in other than a military capacity, and in subsection (*d*) such release is to be granted for "specially urgent reasons of a public character. Such release is only operative for the period during which such emergency lasts." But while the Army Council can issue these orders, it is quite a different matter to get generals and their staffs to act in accordance with even the spirit of these official pronouncements.

Take for instance my own personal experience. I hold a post in civil life the most important duties of which it is impossible to delegate. Though for the first four weeks of the embodiment the brigade was stationed only some 28 miles from my home—an easy 80 minutes run by motor—it was only with the greatest difficulty and unpleasantness we were allowed to leave the town, though a telephone message to my house could have brought me back in less than an hour and a half. For the last two months we have been stationed some 250 miles from my home—and most of our homes—I have had only four days' leave at the end of last month on "urgent private affairs." The brigade has some ten medical officers for about 2000 men, and the general medical officer has tried to help us by always recommending our applications for leave when in his opinion he could do so, and is quite prepared to form a roster for leave which he stated could be done quite consistently with medico-military exigencies. But the brigade headquarters generally refuse the leave, occasionally granting it grudgingly as a special favour. I have, however, after a fight, now obtained four days' leave, but the permission is accompanied by instructions that I must proceed to take immediate steps to divest myself entirely of my civilian liabilities—apparently for quite an indefinite period—an undertaking which I cannot and do not propose to attempt. Moreover, I was told by one of the headquarters staff officers on this occasion that as I was not a volunteer for foreign service I need expect no further leave whatsoever during the embodiment. And the question looms largely in the matter of granting leave—it has been used and is being used as a lever to force Territorials to volunteer for foreign service; and so in spite of Lord Kitchener's and the Army Council's instruction to the contrary, those of us who cannot volunteer for abroad are being penalised and the health and general wellbeing of the community suffer. I am in my fiftieth year, and have, as I have already said, duties which I cannot delegate and domestic responsibilities which I cannot avoid, and I hold that men with less responsibilities should go abroad before citizens of my age and circumstances.

And I submit that there is nothing in the instructions of the Minister of War or the Army Council which prevents a certain amount of leave being granted us for our own interest and in the interest of the community, and there is everything in these instructions to prevent our being penalised because we cannot volunteer for foreign service.

I am, Sir, yours faithfully,

Nov. 2nd, 1914. CITIZEN SOLDIER.

Obituary.

EDWARD McKELLAR, M.D. St. And., M.R.C.S. Eng., J.P.,

DEPUTY SURGEON-GENERAL, BENGAL ARMY (RETIRED).

Deputy Surgeon-General Edward McKellar, who died at Woodleigh, Preston-road, Brighton, on Oct. 27th, had passed the most active years of his life in India, where he served throughout the Mutiny campaign. Son of Dr. Dugald McKellar, he was born at Battersea, and received his early education at Clapham Grammar School and University College, London. Following in the footsteps of his father, he adopted the medical profession and became M.R.C.S. Eng. in 1849, and later was appointed assistant surgeon in the East India Company's Service. He served throughout the second Burmese war in 1852–53 with the 80th Foot, and was present at the capture of Rangoon, Martaban, and Pegu, receiving the medal and clasp for the campaign. He was surgeon in the famous Gwalior contingent which mutinied and massacred nearly all its officers, he himself having a narrow escape, and afterwards served throughout the Indian Mutiny campaign. Subsequently he became attached to the Bengal cavalry for 16 years. During the time he was in India he was in no fewer than 16 engagements. He held many important civil and military appointments and rose to the position of deputy surgeon-general.

In 1870 he graduated M.D. at St. Andrews and soon afterwards settled at Brighton, where he took a lively interest in all local affairs. For many years he was one of the representatives of his parish (Preston) on the Steyning board of guardians. He was manager of one of the Brighton council schools, and as a magistrate for the borough of Brighton proved himself efficient and kindly. He was more or less of an invalid for the last ten years of his life.

Dr. Frederick B. Power is retiring from the directorship of the Wellcome Chemical Research Laboratories. The high character of the research work that has been carried out in these laboratories under his immediate direction is well known to all our readers. Dr. Power will be succeeded by Dr. Frank L. Pyman, whose contributions to chemical science have already been important.

THE WAR.

THE LEGION OF HONOUR.

The President of the French Republic, with the approval of the King, has bestowed the decoration of the Legion of Honour on the following officers of the Royal Army Medical Corps for their gallantry during the military operations between August 21st and 30th, 1914:—*Croix d'Officier:* Major S. L. Cummins. *Croix de Chevalier:* Captain S. E. Lewis, Captain J. T. McEntire, and Captain H. S. Ranken. The last officer has died from wounds received in action.

THE CASUALTY LIST.

The toll of medical lives has been heavy during the past week. Six officers of the Royal Army Medical Corps have been killed at the front, and it is to be feared that the death-roll in the wreck of the hospital ship *Rohilla* will when finally verified contain several medical names. The following are the names of officers in the Royal Army Medical Corps which have appeared in casualty lists since our last issue:—

Killed: Captain Michael Joseph Lochrin, Captain Rupert Henry Nolan, Captain Richard Dominick O'Connor, Lieutenant Reginald Edward Porter, Lieutenant Hugh John Sladen Shields, and Lieutenant David Wylie Rintoul.

Wounded: Lieutenant J. R. Hayman.

Missing: Captain R. V. Dobey.

THE POSITION OF THE BELGIAN MEDICAL MEN AND PHARMACISTS.

A meeting was held on Wednesday afternoon at the offices of the British Medical Association to consider the position of Belgian medical men and pharmacists whose professional position has been involved in the utter ruin which has fallen upon their country, and which has destroyed the whole machinery of the medical profession and its adjuncts. The meeting was convened by Dr. Dawson Williams, Editor of the *British Medical Journal*, and Dr. Squire Sprigge, Editor of THE LANCET, in response to representations made by a provisional Belgian committee, whose representative, Professor C. Jacobs, is now in London. There were present at the meeting Sir Thomas Barlow, Sir Rickman Godlee, Sir Frederic Eve, Sir William Bennett, Dr. Frederick Taylor, Dr. Meredith Townsend, Dr. H. A. Des Vœux, Dr. George Ogilvie, Dr. Alfred Cox (Medical Secretary of the British Medical Association), Mr. Guy Elliston (Financial Secretary of the British Medical Association), Dr. S. Squire Sprigge, Dr. Dawson Williams, with the following representatives of Pharmacists, Mr. E. T. Neathercoat, Mr. F. Pilkington Sargeant, Mr. A. J. Chater, Mr. A. Hagon, and Mr. W. J. Woolcock.

Sir Rickman Godlee took the chair, and, after a brief explanation of the position by Professor Jacobs, the following committee, with power to add to their number, was appointed to make an early report on the procedure to be adopted:—Sir Thomas Barlow, President of the Royal College of Physicians of London; Sir Watson Cheyne, President of the Royal College of Surgeons of England; Dr. Meredith Townsend, Master of the Society of Apothecaries; Sir Rickman Godlee; Sir Frederic Eve; Dr. Frederick Taylor; Mr. E. T. Neathercoat, Vice-President of the Pharmaceutical

Society; Mr. Woolcock, secretary of the Pharmaceutical Society; Dr. H. A. Des Vœux; and Mr. T. Jenner Verrall, the chairman of Representative Meetings of the British Medical Association. Dr. Sprigge was appointed secretary and Dr. Des Vœux treasurer.

The instructions of the meeting to the committee were (1) to communicate with the Belgian Minister and the authorities of the Belgian Relief Fund; (2) to apply to America and other countries if desirable for assistance in the raising of any fund; and (3) to report generally.

MEDICAL RELIEF FOR BELGIAN REFUGEES.

A dispensary has been opened at 265, Strand, W.C., under the auspices of the War Refugees' Committee for the medical treatment of sick Belgian refugees. In the earlier days of the exodus assistance was given at the Aldwych Rink by Voluntary Aid Detachment, London, No. 4, of the British Red Cross Society, under the commandant, Miss Davenport, with such volunteered medical aid as the occasion required. But with the enormous influx of refugees, many of whom only speak Flemish, it was found imperative to organise the medical relief, to secure separate quarters, and to enlist the coöperation of Belgian doctors, many of whom have found asylum in this country. Accordingly, on Oct. 20th, a meeting of doctors who had already been giving their services was held, by the invitation of Dr. J. H. Philpot, at 61, Chester-square, S.W., at which the following were present: Dr. H. A. Des Vœux, Dr. Kielemoes (Melle), Mr. D. F. Maunsell, Dr. Clément Philippe (Brussels), Dr. Victor Philippe (Brussels), Dr. J. H. Philpot, Dr. H. Austin Philpot, and Miss Davenport. It was resolved that those present should constitute themselves into a provisional committee, with Dr. J. H. Philpot as chairman and Miss Davenport as secretary, which, with the authorisation of the War Refugees' Committee, should undertake the management of the refugees' dispensary, and arrangements were made for a continuous service of consultations daily from 10 A.M. to 1 P.M. and 2 P.M. to 6 P.M., and on Sundays from 10 to 11 A.M. The War Refugees' Committee has accepted these arrangements, and the dispensary, though in rather cramped quarters, is now in full working order, with an efficient staff of nurses belonging to the above-named detachment of the Red Cross. The general expenses of the institution are borne by the War Refugees' Committee, but liberal donations have been made by friends of the movement in order that medicines and dressings may be supplied free. Many Belgian doctors now in London, some of whom are well known specialists, have inscribed their names at the dispensary and offered their assistance for consultation in special cases.

PHYSICIANS AND SURGEONS IN A MILITARY HOSPITAL.

At the present time there are a number of hospitals, the General or Base Territorial Hospitals, founded on a military basis in which physicians and surgeons holding commissions in the Royal Army Medical Corps Territorial Forces are serving. There are certain conditions prevailing in them which the medical staff find very different from those they are accustomed to in their civil appointments in the large general hospitals with medical schools. The amount of work to be accomplished and the number of patients to be seen must undergo great variations, and inevitably it is frequently necessary to change the wards from medical to surgical or the reverse. Those in charge of wards, on arrival at the hospital, may find, moreover, that their patients have been removed without their knowledge. This is a necessity, for a telegram may be received from the port at which sick and wounded are being landed that 150 patients are to be received in a few hours, and beds must be found for them somewhere. If the number of wounded exceeds those of the sick some of the medical wards may have to be cleared in order to make room for them; those patients who can be sent to convalescent homes or to their friends being at short notice discharged from the hospital. Further, at a military hospital the War Office officials do not distinguish between physicians and surgeons, and although the difference is fully appreciated and acted on so far as possible by the commanding officer, if the number of wounded is very great it would be quite in accord with right principles if the physicians were asked to take charge of the lightly wounded or convalescent surgical cases. There is a certain amount of routine business which members of the staff may find irksome but which is necessary in a military hospital, such as the formation of "boards" for reports on wounded officers or the discharge of men as unfit for service. These procedures occupy much time, but must be carried out. The General Territorial Hospitals present one aspect which is of the greatest value—namely, that at any time consultations may be held between physicians and surgeons, most of whom hold a high position in their profession, and many of whom have specialised in certain aspects of medicine and surgery. The benefits conferred on the patients are obvious.

THE WRECK OF THE "ROHILLA."

The hospital ship *Rohilla*, which left Queensferry for Belgium to bring back wounded, ran on the rocks half a mile south of Whitby at 4 o'clock on the morning of Oct. 30th. All the boats but one were broken by the seas and washed ashore; the last one was launched, but was swamped when near the shore. Many of those on board were happily rescued by the lifeboats, but a considerable number of lives were lost. All the nurses on board were saved. Further official details are anxiously awaited.

NOTES FROM CHAMBÉRY.

The following is a résumé of experiences extending over some weeks in a hospital at Chambéry, and shows how, as time has gone on, the French organisation has become gradually equal to the terrible strains put upon it. On the whole our correspondent's report makes satisfactory reading, the absence of typhoid fever among the wounded being particularly gratifying.

Soon after the mobilisation order had cleared the district of its healthy male adults instructions were given to make ready to receive the wounded. The town itself is small, only numbering five or six thousand residents, but it offers exceptional facilities for auxiliary hospital accommodation, in that it comprises spacious casinos and many palatial hotels. Within a fortnight, thanks to the active coöperation of private citizens with the constituted authorities, now subordinated to military control, we were able to report 1200 available beds. There was some difficulty with regard to surgical assistance, because all the local medical men under 45 had gone to the front, and those who remained, while equal to ordinary minor surgery, lacked experience in military emergencies. Fortunately, one or two foreign surgeons happened to be detained here by the quasi-impossibility of getting home, and they have been since reinforced by a draft of army surgeons, who have had by this time grand experience in dealing with injuries inflicted by bullets, shells, and shrapnel. So far not a single instance of bayonet wound or sword-cut has come under observation.

The staff was composed for the most part of willing but inexperienced volunteers, male and female,[1] who required to be trained to their duties, though some of them may have gone through a course of Red Cross training—roughly speaking, equivalent to a first-aid course at home. On the whole, this *ad hoc* organisation worked very well because strict aseptic precautions are of less importance when every wound is septic by the time it reaches hospital and when operations are limited to the removal of foreign bodies, bits of dead bone, &c., from septic cavities, and to amputations for gangrene or secondary hæmorrhage in septic wounds.

Speaking generally, nine out of ten wounds have been caused by fragments of shell or shrapnel balls (spherical, about the size of marbles) and only about 1 in 10 of bullet wounds. Bullet wounds with the modern conical, high-speed bullet only seem to be serious: (1) When towards the end of their course their direction is changed by contact with a bone; the impact makes them twist on their transverse axis, inflicting terrible lacerations at the aperture of exit, appearances which no doubt have given rise to the allegations respecting the use of dum-dum bullets. (2) They may traverse or enter a long bone, splitting it right up to the next joint, entailing serious consequences should any septic material such as particles of clothing, &c., have been carried in, or should the wound subsequently become infected, as was invariably the case. (3) These disastrous consequences are intensified when the bullet exerts its effects on the shoulder or hip joint. The head or neck of the long bone involved—femur or humerus—is often shattered with more or less injury to the ilium or scapula, entailing prolonged suppuration and calling for the removal of sequestra, the opening up of pockets, and the maintenance of efficient drainage. These were the cases in which secondary hæmorrhage was particularly apt to occur under circumstances rendering isolation and ligature of the main artery difficult or impossible, so that amputation was the only resort. Even so it often proved fatal. (4) When in wounds of the chest or abdomen septic material is carried in. In the absence of this complication this class of case did remarkably well. Our practice has been only to operate for the removal of foreign bodies when these had proved the starting-point of septic mischief or gravely interfered with function. The only exceptions were cases in which the bullet or metal splinter lay just beneath the skin.

The injuries inflicted by shell and shrapnel bore upon men who were either lying prone or who, on the other hand, were protected by entrenchments. The latter category comprised a large proportion of wounds of the hands and forearms, to be explained by the fact that the men were holding their knapsacks over their heads to ward off the débris of shells. Of the former, the riflemen, the upper part of the back was of course protected by the knapsack, and the effects bore mostly on the buttocks, the backs of the thighs, and legs. Grave destructive lesions of the buttocks were common. I can recall cases in which the buttock was entirely torn away, with or without part of the external genitals, or, it may be, ghastly lacerations of the thigh and formidable injuries to the pelvis. In one instance, now on the road to recovery, the shrapnel ball traversed and splintered the ilium, and could be seen in the radiogram lying inside the pelvis. The man complains of uneasiness in the outer and upper part of the iliac fossa, but nothing can be detected on palpation and he is doing well.

An interesting case was that of a man who received a bullet wound on the right side of the neck two or three inches below and a little behind the lobe of the ear, the aperture of exit being on the left of the last cervical vertebra. He felt as if struck by lightning and lay for two hours, when, as the fire slackened, his comrades pulled him back into the trench. In the evening they carried him on their rifles several miles to a hospital where the wounds, trivial in themselves, were dressed. He was found to be paralysed on the right side, with loss of sensation on *both* sides, though more marked on the right, and there was loss of sensation of the skin on the right half of the abdomen. He became (and remains) very deaf on the right side The face perspired on the left side and not on the right. He has recovered the use of the leg, and movement is slowly returning in the arm. He can now feel a prick or a pinch, but not a mere touch. The skin on the right side seems more sensitive to heat and cold than on the left. Patellar reflex much more marked on right side.

As showing the effects of mere concussion, a man, aged 35, was lying in a grange when a shell crashed through the roof and exploded. He lost consciousness for two hours, though he had only sustained a few scratches. Nevertheless he remained dull and apathetic for several days, taking no interest in what was going on around him. He complained that he was unable to read, and on testing vision it was found that though he could spell the letters of a word he was unable to utter the word; similarly, though he could write the letters of a word seriatim on dictation he could not write the word when pronounced. In the course of a fortnight these symptoms cleared up, though six weeks after receipt of the injury he still hesitated a little before naming the word.

We have had several cases of emphysematous gangrene calling for amputation. Although the adipose tissue in the flaps was yellow, offensive, and gelatinous, these cases did well in spite of some sloughing. There have been many cases with blue or bluish-green pus; they were characterised by profuse suppuration and a horribly offensive odour. Iodoform proved very effectual in these cases.

There have been several cases of tetanus, perhaps a dozen in all (out of a total of 1000 wounded), the symptoms supervening at or about the third week of injury. These were cases of extensive lacerated wounds contaminated with fragments of clothing or soil. They were given repeated doses of anti-tetanic serum, and the spasm was relieved by means of chloroform and chloral. Injections of carbolic acid (Bottini's method) were tried, but did not seem to do any good. The cases all proved fatal in from three days to ten days.

Side by side with these cases of unquestionable tetanus were two of pseudo-tetanus. I call it "pseudo" because in a couple of days the symptoms—severe general convulsions on pinching a muscle, trismus, and opisthotonos—passed off as suddenly as they were manifested, a result which could hardly be attributed to the treatment. The onset was very variable. In one there was muscular twitching for two or three days before the man developed risus and trismus. In another instance the attack was ushered in by a high temperature and diarrhœa, but in the majority trismus and risus sardonicus were the first symptoms.

There were a few cases of typhoid among the wounded, but not more than 3 or 4 per cent. Considering the conditions of life in the trenches and in the active fighting line this does not seem a large proportion. Combatants are often constrained to dwell for days together in the trenches, which serve as dining-room, drawing-room, kitchen, and water closet in one! Several men told me that having crept out of the trenches for sanitary purposes the enemy were inconsiderate enough to snipe them.

The Care of the German Wounded.

The Medical Chief of the German army, Dr. von Schjerning, has issued an official report covering the first two months of war only and referring to the western field of battle. The organisation and the material in aid of the wounded was, he reports, all that could be expected under the specially difficult circumstances due to the great rapidity of march, difficulty of transport, and extraordinary amount of wounded. In one week some 40,000 to 50,000 men with minor wounds were sent home. Often the fields of battle could not be searched for days. All those who could bear transport were sent back to Germany on foot, by carriage, or motor ambulances, or in the luggage vans available. All the trains bringing food and ammunition to the front returned filled with wounded. Those severely hurt were treated in field ambulances or war hospitals near the battlefields. Dysentery and typhoid fever occurred only sporadically. The wounded everywhere were well cared for, and he praises warmly the doctors and ambulance nurses. 9000 medical men were with the troops at the first, west and east, and in the first two months 74 medical men were in the casualty lists.

---

[1] The French Army Medical Service, be it remarked, is made up of surgeons *de carrière* who undergo a special course of training at the Val-de-Grâce medical school, and of civil practitioners attached to the reserve and Territorial regiments who become army surgeons on mobilisation.

THE ORDER OF ST. JOHN OF JERUSALEM IN ENGLAND, AMBULANCE DEPARTMENT.

An appeal is being made by the ambulance department of the Order of St. John of Jerusalem for funds to extend its work amongst the wounded in the war by means of a shilling collection. Already 150 hospitals and convalescent homes have been established and staffed under the auspices of the order; 209 medical men and nurses have been sent out to the front; over 5500 orderlies have been despatched to the expeditionary forces, or distributed amongst the ships and naval and military hospitals; and 748 cases and bales of medical stores and supplies, including 56,000 articles of clothing, have been sent out to the sick and wounded. A depôt for the convenience of the troops has also been established at Southampton, where they can obtain food and medical assistance day and night, and a number of motor ambulances are being despatched to carry the wounded from the front to the base. The offices of the fund are at Marconi House, Strand, where accommodation has been kindly placed at the disposal of the ambulance department by the Marconi Wireless Telegraph Company.

OBITUARY OF THE WAR.

GEORGE HENRY CHISNALL, M.B., B.S. LOND., F.R.C.S. ENG.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

A former teacher writes:—"Perhaps in nothing is the waste of war more apparent than in the loss of those who after years of patient study have slowly perfected themselves in the art of healing only to be blindly crushed at the very outset of their career. The thoughts of many at the London Hospital must have yielded some such reflection on hearing of the death at Poperinghe of George Henry Chisnall, killed by shell fire on Oct. 24th while attached to the 1st Cameron Highlanders. Not only was Chisnall, as his academic distinctions prove, a student of outstanding ability, but he combined with a very thoughtful temperament an originality of outlook, an industry and a tenacity of purpose which persuaded his many friends that he would some day take high position in his profession. The essay on 'Fractures of the Upper Part of the Humerus and their Treatment' with which he won the Jonathan Hutchinson prize at his college was regarded as an earnest of a steady outflow of original work in the future. Personally he was noted for an imperturbable serenity of mind and a geniality of manner which made him beloved by all who knew him. Having held almost all the resident appointments in the gift of the London Hospital, he volunteered for service in the Royal Army Medical Corps at the beginning of the war, with the result which is now so deeply deplored. There only remains to us a memory, and a hope that after all Death may not be the gaunt spectre we imagine. To the Greeks it will be remembered *θανατος* was a thoughtful youth of not unkindly aspect; right in so much, perhaps they were also right in this."

BRIAN COLDEN ANTILL POCKLEY, M.B., CH.M. SYDNEY,

CAPTAIN AND SURGEON, AUSTRALIAN NAVAL RESERVE.

The tragic circumstances under which Captain Brian Colden Antill Pockley, surgeon in the Australian Naval Reserve, met his death on duty with a landing party at Herbertshohe, in German New Guinea, were in themselves of his own unwitting creation through an act of devotion to duty. It seems that Captain Pockley was called to attend to a wounded sailor, and finding that it would be necessary to send him to the rear, covered the sailor bearing him with his own Red Cross coat to indicate that he was engaged on a work of mercy and to procure him immunity from attack. Captain Pockley continued in his shirt sleeves to attend to another wounded man, when he was deliberately shot through the chest by a German officer. This officer was subsequently captured and tried by court martial on one of the warships for a breach of the Geneva Convention. He was, however, able entirely to satisfy his judges that, owing to the absence of any distinguishing mark, he had regarded Captain Pockley as a combatant, not recognising the work on which he was engaged, and so was exonerated from that worst of treacheries, treachery against the Red Cross, the one outstanding humane feature of modern warfare among civilised peoples. Captain Pockley was only 24 years of age, a brilliant scholar, an athlete, most popular with his school and college, and beloved by all who knew him. He graduated only this year at the University of Sydney as M.B., Ch.M. He was the son of Dr. Antill Pockley, of Sydney, who was President of the Australasian Medical Congress when it was held in Sydney in 1911.

DAVID WYLIE RINTOUL, M.B., CH.B. ST. AND.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant David Wylie Rintoul, who was killed in action on Oct. 21st in his twenty-sixth year, was the elder son of Mr. D. Rintoul, of College-road, Clifton. He was educated at Clifton College, and graduated M.B., Ch.B. of St. Andrews University in 1912. During 1912 and 1913 he filled the posts of house surgeon and house physician at the Bristol General Hospital. On resigning to join the Royal Army Medical Corps he received the thanks of the committee of that institution for the manner in which he had performed his duties. Lieutenant Rintoul received his commission early this year, and was attached to the Eastern Command before the outbreak of war.

THE BRITISH RED CROSS SOCIETY.—The summary of work for the week ending Nov. 4th states that the number of auxiliary home hospitals accepted by the War Office to date is 306, containing beds for 10,235, including 2158 beds accepted during the past week, and distributed among the army commands as follows: London, 659; Southern, 3051; Aldershot, 609; Eastern, 3082; Northern, 1506; Western, 1139; Irish, 189. A number of Voluntary Aid Detachments are being utilised in connexion with these hospitals. At the British Red Cross Hospital, Netley, this week it is hoped to have most of the nurses in their own huts, which will give a certain amount of spare accommodation for patients. At present four huts are full of soldiers from the Expeditionary Force and three with wounded Indians of the Expeditionary Force. A regular supply of fruit would be very acceptable for the native patients.

Gifts should be addressed to the Commandant, Sir Warren Crooke-Lawless,

Since last Tuesday evening 83 motor-cars have been despatched to the various centres; these included two lorries and two touring cars, the rest being motor ambulances. As far as offers of cars are concerned there are still a large number of people willing to provide a complete ambulance, and there are many others who are offering their cars for conversion. These, for the time being, have been asked to be placed on the reserve list. Chauffeurs have been registered each day, and at present sufficient are on the books to supply needs as they arise. When the appeal first appeared in the *Times* there were many people who immediately took steps to raise a local appeal for funds to purchase a motor ambulance. These will be accepted when the definite offer comes, but it is hoped that donors will allocate their cheques to running expenses rather than to additional cars. From Oct. 19th to Oct. 27th, inclusive, 9722 wounded were removed from trains to hospitals by the cars of the society, and 2000 were removed from hospitals to ships. From Oct. 15th to Oct. 27th, inclusive, the No. 2 convoy cars at Bethune carried 4116 wounded from the field hospitals to the clearing hospitals.

On the undermentioned dates the personnel was posted for service at the places named: Oct. 29th, Serbia, 6 doctors and 12 orderlies. Oct. 31st, Rennes, 6 doctors and 12 dressers. Nov. 1st, Boulogne, 8 doctors; Rouen, 2 dressers. Nov. 2nd, Boulogne, 4 doctors. Nov. 3rd, Boulogne, 2 doctors and 15 dressers. Oct. 31st, Rennes, 28 nurses. Nov. 1st, Boulogne, 30 nurses. The following nurses were also supplied for home service: Oct. 30th, Mansfield, 4. Oct. 31st, Ongar, 3; Southampton, 6; Wigan, 1. Nov. 2nd, Bristol, 1; Louth, Lincolnshire, 1; Margate, 2; Winchester, 2. Nov. 3rd, Bicester, 1. Gerrard's Cross, 5; Perth, 1; Reigate, 3. 5525 collecting boxes have been issued and 1454 returned, and the sum of £3083 13*s*. 3*d*. has been collected to date. No further boxes are to be issued for use in the streets or public places.

The following stores and transport have been despatched during the past week: Boulogne, 470 cases; Rouen, 197 cases; Calais, 96 cases; Dunkirk, 60 cases; St. Malo, 21 cases; Dinard, 7 cases; Paris, 3 cases; Tarbe, 3 cases; Serbia, 37 cases. Total, 894 cases and bales. These represent hospital stores, garments, and supplies of every sort and kind. The demands made from Boulogne and Calais have been exceptionally heavy, owing to the large amount of wounded arriving at these two places. Stores at Rouen have been largely replenished. Five ambulance ships have been regularly supplied with garments and comforts for the wounded crossing the channel. 70 hospitals in the British Islands have been supplied with what they have requisitioned for. Medical stores to the amount of £691 6*s*. 6*d*. have been purchased.

JOINT RED CROSS COMMITTEE.—The joint committee of the Order of St. John of Jerusalem in England and the British Red Cross Society which was announced in these columns last week has now met, and confirmed the election of the Hon. Arthur Stanley as its chairman and Sir H. C. Perrott as its vice-chairman.

EDINBURGH AND THE WAR.—At the half-yearly meeting of the University Court held on Oct. 30th the convenor of the business committee referred to the part taken by the University of Edinburgh in the war. It must, he said, be a matter of the greatest gratification to all her sons and daughters to know that their University had made a noble and magnificent response. There were no fewer than 12 members of the University staff at present serving in His Majesty's Forces. Principal Sir William Turner said with reference to the compilation of a roll of honour that several of his colleagues who had taken a prominent part in connexion with the arranging for the entry of these graduates and students into the military forces had already commenced the formation of a list, but it was obvious that it would not be easy to trace some 700 persons, and there would be a difficulty in obtaining a full list.—On the same afternoon a train arrived at Princes-street Station with 64 Belgian wounded on board. A staff of stretcher-bearers and a fleet of motor ambulances and motor-cars conveyed the patients to Craigleith Hospital. All the men had been in the battles of Nieuport and Dixmude, and as indicating the hard nature of the fighting the arrivals, except for some half-dozen men, were stretcher cases.—At a meeting of the Edinburgh Royal Infirmary managers held on Nov. 2nd, Lord Provost Inches presiding, Mr. Crole, K.C., referring to the recent visit to the infirmary of Sir Spencer Ewart, K.C.B., commanding the forces in Scotland, and Admiral Sir R. S. Lowry, K.C B., senior officer on the coast of Scotland, said the infirmary was taking the wounded sailors and soldiers on the same footing as ordinary patients; the War Office and Admiralty were not charged anything for the institution's care of them. Some of the wounded had had their clothes on for six weeks when they arrived at the infirmary. One of them, a reservist in the Gordon Highlanders, had mentioned that from the time he had left Aberdeen till he had been put to bed in the infirmary he had never had his clothes off. One could well understand the condition such clothes were in, and the consequence was that those soldiers required a new outfit on leaving the institution. The infirmary had no clothes to give them, but he was glad to say that on application to the Lord Provost's committee they were promptly supplied with clothes of all sorts.

PROFESSIONAL CLASSES WAR RELIEF COUNCIL.—In our last issue we announced the formation of this council, and indicated its objects and proposed methods. We are now asked to state that Mr. J. Pierpont Morgan has generously lent to the council Nos. 13 and 14, Prince's-gate, S.W., for a maternity nursing home for the period of the war, and that furniture and equipment are needed—house- and table-linen, blankets, cutlery, plate, screens, bassinettes, and baby-clothes. Offers of help in the way of gifts or loans should be made in the first instance to Mrs. Hills, 32, Prince's-gardens, London, S.W.

The home will have a voluntary medical staff of many well-known medical men and women, and a voluntary nursing staff of excellent certificated nurses. There is in it every requirement for perfect comfort and good nursing, and here the wives of professional men will be received throughout the war, and the period of distress ensuing, for the sum of two guineas a week during the time they are in the home, which sum will be absolutely inclusive. The council hope that medical men will assist them in making the existence of the home known to their patients. Many doctors are, it is well known, generously giving their services free to women who find themselves unable to meet the expense; but this generosity cannot continue on any large scale without seriously dislocating their own profession, therefore the establishment of this home should be the solution of many difficulties. It is also hoped in time to establish similar homes in the provinces, and this might well be done by local effort, in imitation of, and in coöperation with, the council's home in London.

The home will be open both to those who are recommended through the professional institutions and societies, and to those who apply direct to the Council. In the former case the weekly fee may be paid by the benevolent fund of the husband's institution, in the latter either by the patient or friends, or by the central fund of the council augmented by the special maternity fund which has been raised for the purpose by the members of the Eugenic Education Society.

The committee under which the maternity aid scheme is run consists of the following:—Dr. Mary Scharlieb (chairman), Sir Francis Champneys, Dr. H. C. Barnes, Dr. Maud Chadburn (senior obstetrician, New Hospital for Women), Mrs. Theodore Chambers, Mr. Chatfield Clarke (president Surveyors' Institution), Miss Graeves (matron, City-road Lying-in Hospital), Muriel, Lady Helmsley (chairman, London Day Nurseries Association), Dr. H. Simson, Dr. Samuel West (treasurer, Royal Medical Benevolent Fund), Dr. Florence Willey (Royal Free Hospital for Women), and Mrs. Hills.

SOLDIERS AND VENEREAL DISEASE.—A committee of the Liverpool Medical Institution, acting in concert with an influential lay committee, have entered upon a campaign against venereal disease. With the special object of warning young soldiers against the dangers which beset them from this cause the committee have now published two specially written pamphlets. One is entitled "The Dangers of Venereal Diseases," being an instructive inaugural address by Dr. Charles J. Macalister, chairman of the medical committee, and the other entitled "Some Dangers a Soldier may Avoid," written in a very simple and direct style, by Dr. R. W. MacKenna, honorary treasurer. The committee are anxious to interest commanding officers, chaplains, medical men, and others who are in a position and who would undertake to distribute these pamphlets among those for whom they are intended. They will be supplied free so far as funds admit. Correspondence is invited, and letters addressed to the Librarian, Liverpool Medical Institution, will receive attention.

British Nurses for French Military Hospitals.—An organisation under the title of "The French Flag Nursing Corps" has received a communication from the French Minister for War, dated Sept. 29th, asking for 300 fully trained British nurses to take service in the French military hospitals in the districts of Rouen, Le Mans, Rennes, and Nantes. Through the instrumentality of Sir Thomas Barclay and his niece, Miss Grace Ellison, a committee has been formed, which has been authorised by the Minister of War for France to select the nurses to be sent out and to undertake the necessary organisation. The French Ministry of War (Service de Santé section) has undertaken all financial responsibility for the nurses' salaries, travelling expenses, &c., the preliminary financial arrangements being in the hands of the French Consulate in London. Suitable provision has also been made for the supervision and comfort of the nurses. One detachment of nurses has already been despatched, and is now at work among the wounded in the military hospitals at Rouen, and further detachments are being sent out weekly as required. Applications from fully qualified nurses, particularly from those who can speak French, may be sent to Lady Barclay, 60, Nevern-square, S.W., or to Mrs. Bedford Fenwick, 431, Oxford-street, W. The medical advisers to the committee are Dr. R. Murray Leslie and Dr. J. Dundas Grant.

Chloroform in France: an Alleged Shortage.—In a letter which has appeared in the lay press it is stated that in various parts of France the hospitals for our wounded allies are in need of chloroform, and that amputations as well as minor operations have had to be performed without anæsthesia. We have not been officially informed of any such shortage of anæsthetics on the part of medical men working under the Croix Rouge, and we trust that the difficulty, if it exists, in securing adequate supplies of chloroform in France is at most only local and temporary. British manufacturers would, we are certain, take instant steps to meet any deficiency which was brought to their notice through responsible sources.

Asiatic Cholera in Austria.—According to official reports issued in the *Wiener Medizinische Wochenschrift* of Oct. 18th, 157 cases of Asiatic cholera all bacteriologically examined occurred from Oct. 6th to 12th in the Austrian empire. The first cases have invariably been imported through soldiers or fugitives from the seat of war. They refer to a few isolated cases in some 40 localities. Larger numbers were only reported from Budapest (6), Vienna (16), Neer-sandeck (16), and Gorlice (20). At the same time the hospitals of Vienna announced 27 cases of enteric fever and 175 of dysentery as having occurred from Oct. 4th to 10th.

Medical Attendance on Dependents of Irish Sailors and Soldiers.—The Irish committee of the British Medical Association has addressed a request to medical practitioners in Ireland to join in a scheme for giving free medical attendance to the dependents of sailors and soldiers on active service with His Majesty's forces. The details of the scheme are the same for Ireland as for Great Britain.

The International Board of Health.—We learn from a correspondent in Constantinople that this Board has practically ceased to exist as an international body, and is sitting as a Turkish body without foreign delegates.

The University of Paris and Belgian Students.—The authorities of the University of Paris have decided unanimously that the students who had matriculated and entered any Belgian university before the war could be received as duly matriculated students at various faculties of the University of Paris without further form. Belgian students at secondary schools will also be taken at the University of Paris if they have fulfilled the conditions precedent to matriculation and entry at one of their own universities. Those who have no school certificates in proof of this position can have recourse to diplomatic or consular agency in support of their claim to admission.

Medical News.

University of Oxford.—At a Congregation held on Oct. 29th the following degree was conferred:—

M.D.—Arthur Duncan Gardner, University College.

University of Cambridge.—At a Congregation held on Oct. 31st the following medical degrees were conferred:—

M.D.—A. Feiling, Pembroke; and A. Abrahams, Emmanuel.
M.B., *B.C.*—C. G. H. Campbell, St. John's.
M.B.—R. A. Ramsay, Caius.
B.C.—F. G. Lescher, Caius.

University of London.—Colonial Examinations.—At the First Examination for Medical Degrees held recently the following candidates were successful:—

Ceylon (Colombo).

John Robert Blazé and Simon Reginald Gunewardene, Ceylon Medical College.

Nobel Prizes.—It is now reported that the conferring of these prizes for the year 1914 for literature, medicine, chemistry and physics will be postponed until next year. Our Paris Correspondent referred to the prizes on Feb. 14th last, indicating that the French choice had fallen upon Professor Bouchard.

Society of Medical Officers of Health.—Dr. W. J. Howarth, medical officer of health of the City of London, will read a paper at the next meeting of this society on Nov. 13th on the subject of the Marking of Meat. The meeting will be held at 1, Upper Montague-street, Russell-square, London, W.C.

Queen's University of Belfast.—In connexion with the will of the late Mr. W. Gibson, chairman of the Goldsmiths' Company, Regent-street, London, and of Belfast, a sum of £10,000 has been left upon trust for investment to form a "Gibson Scholarship Fund" at Queen's College, Belfast, of which the income is to be applied in the encouragement of education in agriculture and the management of land for profit by the establishment of "Gibson Scholarships" for resident undergraduates of the College, being sons of farmers in the counties of Antrim and Down. When the University was established Mr. Gibson presented a silver mace. By his will he has bequeathed £1000 to the Royal Victoria Hospital, Belfast, for a "Sarah McLees Cot," in memory of his late niece. On Oct. 21st a meeting was held in the Great Hall of the University to consider the call of duty in the present national exigency. Speeches were made by senators and professors urging the students to go to the front. A resolution was passed recommending that efforts should be made to have a special University company organised in one of the local service battalions, and that all members of the University who are fit for military service should consider the propriety in the present emergency of suspending their customary amusements and either joining the proposed University company or applying for admission to the officers' training corps. A movement is also on foot to form a Queen's University veterans' corps, the age-limit of those joining to be between 38 and 60 years, and graduates and other alumni bordering on these ages have been asked to attend a meeting in the University on Oct. 29th to discuss the matter.

Royal Medical Benevolent Fund.—At the last meeting of the committee 37 cases were considered and grants amounting to £303 voted to 32 of the applicants. The following is a summary of the cases relieved:—

Daughter, aged 42, of M.R.C.S. Eng. who practised at Shrewsbury Training for rescue work. Mother died recently and the little income she had was only for life. Applicant required a little help until able to commence work. Voted £5.—Widow, aged 42, of L.R.C.P. & S. Irel. who practised in Ireland and Australia. Usually earns her own living as a teacher of languages; was in Berlin at a post when the war broke out and had to return to England without her belongings or money. She proposed to go to Madrid where she could obtain work. Previous grant, £10. Voted £5 as gift and £7 as a loan.—Widow, aged 66, of M.R.C.S. Eng. who practised at Notting Hill. Has five daughters, one a trained nurse who has had to give up her post to nurse her mother who is suffering from malignant disease in the breast. Try to make a little by letting room. Relieved 14 times, £176. Voted £5.—M.R C.S., aged 81, who practised at West Kensington. Has the old-age pension and a pension from another charity. Is blind. Has four children, the eldest of whom is practically blind and the others unable to help. Relieved twice, £14. Case referred for further inquiry and the sum of £5 placed at the disposal of the visitor.—Widow, aged 63, of M.B. Glasg. who practised at Carnarvon. Unable to work and only income £16 from investments and 5s. per week temporarily from brother. Three children married and unable to help. Relieved twice, £12 Voted £12 in 12 instalments.—Widow, aged 46, of L.S.A. Eng. who practised at Leyton. Left with five daughters, ages 9 to 16 years. Very delicate and only able to do very light work. Hopes to take in paying guests and wishes to remove to a more suitable house. Voted £10 towards removal expenses.—Widow, aged 39, of L.R.C.S. & P. Irel. who practised in Monmouthshire and New South Wales. Acts as working housekeeper at about £15 per year and her youngest child is allowed to live with her. Eldest child, aged 12 years, adopted by grandparents. Wants assistance towards the education of daughter aged 11 years. £10 voted through the Guild who were also going to assist.—Widow, aged 67, of M.B., B.S. Lond. who practised at Islington. Only very limited means. Eldest son used to help, but owing to the falling off of his business unable to continue. Endeavouring to obtain an Epsom College pension. Voted £12 in 12 instalments.—Daughter, aged 48, of M.D. Glasg. who practised at Glasgow. Endeavours to make a living by letting rooms at a seaside resort, but owing to short season in consequence of the war is unable to meet her expenses. Voted £10.—Daughter, aged 35, of M.R.C.S. who practised at Streatham. Very delicate and only a few pounds per annum from an investment. Supplements this by painting, but no market for pictures at present. Voted £5.—Widow, aged 58, of L.R.C.P. Dub. who practised in London. Endeavours to make a living by taking boarders and nursing mental cases, but in consequence of recent illness has not been able to attend to this thoroughly. Voted £10.—Daughter, aged 56, of M R.C.S. Eng. who through ill-health was unable to practise. She is suffering from carcinoma of the breast and too ill to work. Only income £16 10s. per annum. Voted £12 in 12 instalments.—Widow, aged 60, of M.D. Glasg. who practised at Burnham and was an annuitant of the Fund. She is a confirmed invalid and unable to help herself. Only small income provided by friends. Voted £12 in 12 instalments.—Widow, aged 35, of M.R.C.S. Eng. who practised at Bexhill-on-Sea. One child 4 months old. Left totally unprovided for. Voted £3 and the case referred for report.—Widow, aged 35, of M.R.C.S. Eng. who practised at Monmouth and was killed at the front. Widow left with two children, 3½ and 1 year. Voted £25.—Widow, aged 58, of M.R.C.S. Irel. who practised at Newnham-on-Severn and died two years ago, leaving widow and family penniless. Two daughters, one of whom is a nurse at the front and one son at the front. Only income 15s. per week allowed by children. Relieved once, £10. Voted £10 in two instalments.—Widow, aged 42, of M.B. Edin. who practised at Sheffield. Health very bad and unable to obtain suitable employment. One son being educated by grandparents. Promise of light work when a little stronger. Relieved once, £10. Voted £10.—Widow, aged 49, of M.R.C.S. Eng. who practised at Bexhill. Tries to earn a living by taking boarders, but it requires six to make it pay and only has three at present. Two daughters, ages 19 and 10½; eldest a clerk who is only able to contribute £12 per annum. Relieved twice, £20. Voted £10.—Daughter, aged 60, of M.R.C.S. Eng. who practised at Hackney. Applicant is blind. Only income an annuity from another society and £12 from friends. Relieved four times, £34. Voted £12 in 12 instalments.—Daughter, aged 61, of M.D. Lond. who practised in London. Is quite blind. Only income a pension of £20 from the Blind Society. Relieved twice, £18. Voted £12 in 12 instalments.—Widow, aged 65, of L.R.C.P. Edin. who practised at Port Carlisle. Suffers from cardiac asthma and recently operated on for carcinoma of the breast. Left without any means, and of the five children only youngest daughter able to help with 10s., for which she has her board. Relieved once, £12. Voted £12 in 12 instalments and referred to the Guild.—Widow, aged 59, of M.D. Dub. who practised at Acton. Endeavours to earn living by taking boarders, but has not been successful lately. Son, who usually pays rent for her, unable to continue owing to war. Relieved once, £10. Voted £5.—Widow, aged 55, of M.R.C.S. Eng. who practised at Kensington. Successfully earned a living of late by taking boarders, but the four she recently had have all joined the army so she is now without. Relieved once, £10. Voted £10 in two instalments and referred to the Guild.—Widow, aged 63, of M.R.C.S. Eng. who practised at Newtown, North Wales. Very poor health and heart trouble. Eldest son abroad has in the past paid her rent, but is now unable to do so on account of ill-health. Six children, the youngest unable to work on account of ill-health and the others unable to help. Relieved six times, £55. Voted £15.—Daughter, aged 52, of L.R.C.P. Lond. who practised at Birmingham. Endeavours to make a living by letting rooms, but owing to short season has not made much this year. Eyesight very bad. Relieved three times, £32. Voted £12 in 12 instalments.—Daughter, aged 55 years, of M.R.C.S. Eng. who practised in London. Suffers from chronic glaucoma and general bad health. Only income £24 per year. Relieved six times, £55. Voted £12 in 12 instalments.—Widow, aged 52, of L.R.C.S. Edin. who practised on the West Coast of Africa. Endeavours to earn a living by letting rooms and nursing. One invalid daughter at home and two sons abroad unable to assist. Relieved three times, £36. Voted £12 in 12 instalments.—Daughter, aged 68, of M.R.C.S. Eng. who practised at Keynsham. All money lost by the foreclosure of mortgages. Tries to earn a little by painting, but has found it difficult recently in obtaining clients. Relieved once, £12. Voted £18 in 12 instalments.—Widow, aged 55, of M.R.C.S. Eng. who practised at Donhead, and who had been a recipient of help from the Fund. Unable to work. Has one daughter unable to assist. Since husband's death a sister has assisted her, but cannot now continue. Voted £2 and referred to the Guild for report.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

THE "LONDON PANEL COMMITTEE GAZETTE."

We have received from members of the London Panel Committee copies of the first number of the *London Panel Committee Gazette*, a pamphlet of four pages, which is stated on its first page to be "circulated only to practitioners on the London panel," and which ostensibly is issued to those gentlemen by the London Panel Committee. We say "ostensibly" because, although a note on the last page intimates that communications should be addressed to the secretary of the Panel Committee, it is difficult to believe that that body, having before it a copy of the "Gazette," deliberately, and with anything like unanimity, sanctioned its publication. Regarded as an official publication it is a surprising document. A page of short paragraphs, entitled "What We Think," is composed in a style which many readers will find offensive. This is followed by observations upon "Economy in Prescribing," apparently prompted by the London Pharmaceutical Committee having asked the Panel Committee to make investigations under Article 40 of the Medical Benefit Regulations into certain cases of alleged extravagant prescribing. Allusion to this reference from the Pharmaceutical Committee is followed by various paragraphs on over-prescribing, including a statement that "a rapid scrutiny of the prescriptions suggests that a considerable portion of the charges upon the drug fund could have been avoided without loss of efficiency, and even with positive advantage to insured patients, by properly directed economy in prescribing." The charges of over-prescribing referred to the Panel Committee are grave matters for careful and judicial consideration, and if the committee has really formed an opinion after a "rapid scrutiny" of the prescriptions involved, we cannot commend the policy of making known views so arrived at. We hope, however, and indeed believe, that the Panel Committee has not either formed an opinion prematurely upon the cases in question or sanctioned any intimation to that effect, and that the observation quoted is intended to be of general rather than particular application. If so, however, it is expressed in unfortunate terms. The duty of the Panel Committee is, after hearing both sides—that of the Pharmaceutical Committee and that of the practitioners—to report to the Insurance Committee, which in its turn will deal with the cases referred upon their individual merits. Its duty, so far as particular cases are concerned, is limited to this. There should be no harm, as, we believe, will be generally agreed, in a Panel Committee making known to practitioners on the panel, as a matter of general information, its views upon over-prescribing and the principles upon which it will act in judging cases in which this is alleged. The information should, however, be contained in circulars of more dignified tone, and more in accordance with usage than the first number of the *London Panel Committee Gazette*.

SOLUROL.

To the Editor of THE LANCET.

Sir,—I would be obliged if any medical man who has used "Solurol" in the treatment of gout and rheumatism would state his experience of it in your columns.

I am, Sir, yours faithfully,
Margate, Nov. 4th, 1914. P. Newell.

INSURANCE AGAINST TWINS.

In The Lancet of March 7th, 1914, p. 727, we reported that a popular weekly paper had promised to give £5 to every mother of twins born in the United Kingdom, the Channel Islands, and the Isle of Man during the month of July, 1914, on condition that applicants sent with their application a certain number of coupons cut from weekly issues of the paper. We now learn that over 500 applications for the bounty have been received.

THE PLAGUE IN ANTIQUITY.

THE actual nature of the various plagues recorded as having occurred in antiquity seems a never-ending source of discussion. For a long time they were all regarded as identical with pestis bubonica. Recently efforts have been made to show that the plague of Athens in the time of Pericles was not plague, but typhus fever or cholera. (See THE LANCET, Oct. 17th, 1914, p. 968.) Dr. D. Fraser Harris, in a paper reprinted from the *Canadian Medical Association Journal* for July, 1914, discusses the significance of the five golden "emerods" and the five golden mice that were placed in the Ark, which, in the light of our present knowledge of bubonic plague, suggest that the plague referred to in I. Samuel VI. was bubonic plague. The word "emerods," an old form of "hæmorrhoids," occurs in several places in scripture, which suggest that it was used more or less generally for a small tumour—in this case, the buboes of plague. The mice suggest a shrewd appreciation of the connexion between the plague of mice and the subsequent epidemic disease that was characterised by the presence of buboes.

THE CENSUS OF LONDON.

ALL the varied information relating to the County of London collected at the Census of 1911 has now been brought conveniently together in the form of a separate Blue-book and presented to both Houses of Parliament. A table devoted to statistics of the occupations of the inhabitants gives the following figures under the heading of "Medical":—Physicians, surgeons, and registered practitioners, 4488 males. 147 females; dentists (including assistants), 1179 males, 56 females; midwives, 475; sick nurses and invalid attendants, 327 males, 16,126 females; subordinate medical service, 828 males, 863 females.

SELF-CURE.

A READER in the North of England sends us the following extract from the *Leeds Post* of Nov. 2nd:—

> The Self-Cure Remedy Company (Limited) have been registered as a private undertaking, with a capital of £250 in £1 shares, to deal in hygienic appliances and literature, herbal and patent medicines, to teach the principles of hygiene, &c. The subscribers are Mr. G. Hall and Miss E. Horden, both residing at Newcastle-on-Tyne.

We agree with our correspondent that the business appears to be unqualified medical practice of a not particularly blushing kind, but so long as the lady and gentleman who conduct it avoid the assumption of medical titles they are within the law—as at present constituted.

"THE LANCET" HYGIENIC TESTS FOR GAS FIRES.

IN our issue of Oct. 17th last we recorded the results of the hygienic testing of three gas fires submitted to us by the Planet Foundry Co., Limited, of Guide Bridge, near Manchester. They were quite satisfactory, but we suggested that "the maximum consumption of gas in these stoves might with advantage be increased in order to extend upwards the incandescence of the 'radiants.'" We are now informed that these fires are fitted with "a gas and air adjuster," which can be operated to suit the varying pressures and qualities of the gas supplied. This we find to be the case. A further important point about this adjuster is that it can be set so as to avoid the irritating "purr" so common to gas fires, and the result is practically a quiet fire. The principle on which this adjuster works is based upon the distribution of the gas into small parallel streams, which is effected by means of a screw-controlled plug, the periphery of which consists of a series of graduated grooves. These work in a sleeve having an internal collar of definite length. The orifices from which the gas issues can thus be enlarged or reduced as the plug is moved backward or forward. We welcome these attentions to detail, for these things do much to improve gas as a heating agent for domestic purposes.

SHRAPNEL.

THE word is on everybody's tongue, but it is not everybody who knows its origin. Henry Shrapnel, an English artillery officer, the youngest son of a family of nine children, was born on June 3rd, 1761, and entered the Royal Artillery, and visited Newfoundland, Gibraltar, and the West Indies while still a mere boy. He served also in the army of the Duke of York in Flanders, and was wounded at the siege of Dunkirk in September, 1793, and now just 121 years afterwards his invention is in great use not many miles from the very same place. He devoted all the time and money he could spare to inventions in gunnery, and his case-shot or shell was recommended by the Board of Ordnance for adoption into the service. He was afterwards employed at the Royal Arsenal at Woolwich perfecting his inventions. In 1804 his shell was employed in the attack on Surinam, and favourably reported upon, and he later received flattering testimonials as to its efficacy from the Duke of Wellington, Admiral Sir Sydney Smith, and other notable commanders.

D. T. I.—We find that no book is in existence to supply the place of Porter and Godwin's useful "Surgeon's Pocket Book." It is much to be regretted that no authority in the Army Medical Service has brought this work up to date.

J. O.—British Red Cross Society, Manchester Branch. Apply to Major J. Sington, 20, Princess-street, Manchester.

Dr. Mary Cowhy.—The address of the Medical Defence Union is 4, Trafalgar-square, London, W.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Mr. W. L. Balls and Mr. F. S. Holton: Analyses of Agricultural Yield. Part I., Spacing Experiments with Egyptian Cotton (communicated by Dr. F. F. Blackman).—Mr. J. McIntosh and Mr. P. Fildes: The Fixation of Arsenic by the Brain after Intravenous Injections of Salvarsan (communicated by Prof. W. Bulloch).—Mr. A. E. Everest: The Production of Anthocyanins and Anthocyanidins, Part II. (communicated by Prof. F. Keeble).—Mr. H. M. Woodcock and Mr. G. Lapage: Living Observations on the Life-cycle of a New Flagellate-helkesimastix Fæcicola: together with Remarks on the Question of Syngamy in the Trypanosomes (communicated by Prof. S. J. Hickson).—Mr. S. W. Patterson: The Antagonistic Action of Carbon Dioxide and Adrenalin on the Heart (communicated by Prof. E. H. Starling).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY.

SECTION OF SURGERY: SUB-SECTION OF PROCTOLOGY (Hon. Secretaries—P. Lockhart Mummery, W. Sampson Handley): at 5.30 P.M.

Mr. Aslett Baldwin: (1) Case of a Woman, aged 76½, after Abdomino-perineal Excision of the Rectum; (2) Notes of a Case of Gumma of Rectum in a Woman.

Mr. Ivor Back: Notes of a Case of Œdema of the Sigmoid Mesocolon.

Mr. Sampson Handley: Case of Apparently Inoperable Carcinoma of the Rectum becoming Operable under Radium Treatment.

Paper:

Mr. P. Lockhart Mummery: Injuries to the Bowel from Shell and Bullet Wounds.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries—Thomas H. Kellock, David Forsyth): at 8 30 P.M.

Clinical Cases will be shown at 8 P.M.

Paper:

Mr. W. G. Spencer: Case of Retroperitoneal Prolapse of the Spleen into the Left Loin.

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—8.30 P.M., Council Meeting. 9 P.M., Papers:—Dr. A. Morison: Pernicious Anæmia.—Dr. A. W. Robertson: The Toxic Anæmias of General Practice.—Followed by a discussion.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY—9 P.M, Mr. J. M. G. Swainson: Deformities, with Special Reference to Treatment. (Lantern Demonstration.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Fitz-Patrick Lecture:—Dr. C. A. Mercier: Leper Houses and Mediæval Hospitals.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. [illegible] P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynæcological (Dr. J. B. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Nose, Throat, and Ear (Mr. H. D. Gillies). X Rays and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 4.30 P.M., Special Demonstration of Selected Cases of Children's Diseases (Dr. T. R. Whipham). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:- Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Disseminated Sclerosis.

FRIDAY.—3.30 P.M., Lecture:—Dr. H. Tooth: Clinical Cases.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

CENTRAL LONDON THROAT. NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3 P.M., Demonstration of Cases:—Dr. Abercrombie: Pharynx and Naso-Pharynx.

FRIDAY.—3 P.M., Lecture:—Mr. Stuart-Low: Pharynx and Naso-Pharynx.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. K. Sibley: Electrical Treatments—X Rays, Radium, High Froquency.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Eczema in all its Stages.

CHADWICK PUBLIC LECTURES, Bedford College, Regent's Park, N.W.

SATURDAY.—3.0 P.M., Dr. A. T. Nankivell: Camp, Ship, and Hospital Hygiene—I., Our Soldiers' Health in Peace and War (illustrated with lantern slides).

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Medical and Surgical Cases.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Bradshaw Lecture

ON

SOME CLINICAL CONTRIBUTIONS TO THE STUDY OF GLYCOSURIA.

Delivered before the Royal College of Physicians of London on Nov. 3rd, 1914,

By NESTOR TIRARD, M.D. Lond.,
F.R.C.P. Lond.,
PROFESSOR OF MEDICINE, KING'S COLLEGE; SENIOR PHYSICIAN, KING'S COLLEGE HOSPITAL, ETC.

Mr. President and Gentlemen,—The Bradshaw lecture, under the terms of its foundation, may be on some subject connected with either medicine or surgery. For many years past the study of glycosuria and diabetes has been vigorously pursued by experimental methods, yet I venture to hope that clinical observations of these conditions may still have practical bearing upon our conceptions of the etiology, the prognosis, and the treatment. Although glycosuria and diabetes ordinarily belong to the province of the physician rather than to that of the surgeon, there are many occasions upon which these two branches of the profession must act conjointly. From clinical observations I hope not only to throw out some light for the guidance of surgeons in some of the difficulties which arise, but also to show that my subject to-day combines both elements of the terms of the foundation of the Bradshaw lecture.

The Nature of Glycosuria.

While all results of experiment are entitled to careful consideration, many clinicians feel that we are perhaps devoting too much attention to the results of one phase of laboratory work, while scarcely sufficient stress is being placed upon another—viz., the definite result of careful chemical and clinical research. I have long been of opinion that in glycosuria and diabetes we are dealing with defective vital processes which may have no constant underlying pathological change. In other words, I have been tempted rather to look for numerous causes of perversion of physiological processes, instead of attempting to fix upon any single factor for glycosuria.

A study of the history of the contributions to our knowledge of this condition would, I believe, warrant the following propositions:—

1. From the clinical side it might be assumed that glycosuria is encountered under too many varying conditions for it to be due to one constant pathological change.

2. In spite of laborious research no one pathological change has hitherto been demonstrated. As Dr. Saundby has remarked, "The most important common lesion is the wasting of the pancreas," but he does not mean "common to all," since he has enumerated many cases in which the pancreas was either normal or enlarged, instead of being atrophic. Indeed, out of 27 cases he examined, only 13 showed atrophic changes of the pancreas; in the others the pancreas was enlarged, congested, or normal.

3. Glycosuria must be regarded as a perversion of a natural physiological process, and the importance of the condition depends upon the extent and duration of this perverted process. It would appear legitimate to compare the change with the perverted growth of natural cells, which is considered to be the underlying factor of cancerous growths.

4. When endeavouring to trace the cause of a perversion of a natural process we must not expect to be able to demonstrate gross lesions on the post-mortem table. Lesions may certainly be found if the perversion has been long continued, but, since the process is vital, changes must be sought in the method of working rather than in the structure. In cases of long duration the structure of various organs is necessarily altered as a result of the disease, as Dr. Saundby has remarked, but in all probability the negative results of post-mortem investigations may be due to the rapidity of the termination, which often leaves all parts wasted, without incriminating any special organ. The general machinery shows the result of lack of coördination of work, but the cause for the lack of harmony can only be found while the machinery is in action. Similarly, we cannot expect to derive certainty of information from physiological experiments in which the conditions are so far removed from those of human life. Post-mortem observations and physiological experiments are indeed of great value in suggesting lines of possible explanation, but I believe we are likely to get nearer the truth by a careful consideration of the data supplied by pathological chemistry. These data, in turn, must be checked by clinical deductions.

Graphic Records.

I should like now to direct your attention to various observations which have been carried on under my direction for many years past. The first step of an independent nature arose from my dissatisfaction with the ordinary mode of collecting and tabulating the results of analysis of the urine. It has long been customary (and it is indeed the only method) to receive reports upon small samples of the urine, and these reports appear in terms of the relative proportion of sugar in the particular specimen examined. This report is made in the form of so many grains of sugar to the ounce of urine, or of so much per cent., and the value to be attached to these figures must be calculated from a knowledge of the amout of urine passed in the 24 hours. This is, of course, a perfectly simple matter to estimate, if careful records are kept of the quantity passed. We have merely to multiply to get the amount of sugar eliminated on any particular day. The result, however, is that we obtain a chart indicating in a series of columns the quantity of liquid taken, the quantity of urine passed, the amount of sugar in grains per ounce, and the calculated number of grains of sugar passed in the 24 hours. Although such a chart is of considerable value, it is a little difficult to estimate the course of the case when dealing merely with columns of figures, and there is no doubt that daily variations would be more easily appreciated if they could be represented graphically.

The first step, then, that was taken was the preparation of a chart like a temperature chart, which should show daily the total quantity of sugar as estimated from the examination of the mixed specimen of known volume. In following the curve it was easy to see at a glance what daily variations resulted from different modes of treatment or of diet. Charts prepared in this way merely served at first to confirm much of our previous knowledge of the various types of glycosuria and diabetes. They graphically indicated the important distinctions between diabetes occurring early or late in life, and they further showed how often the glycosuria of the aged could be regarded as a trivial matter, readily controlled by due modifications of diet. There is no novelty in this, but the graphic chart certainly made the observations more obvious.

Having realised the utility of this chart, the next step was to indicate alterations in the weight of the patient, and by assigning a different value to the divisions of the chart it was possible to represent these changes in graphic form. For a length of time the charts we employed remained in this simple form, but in view of Graham Lusk's observations upon the dextrose: nitrogen ratio (D : N) we hoped that information of some value might be derived from similarly recording upon the same chart the daily estimation of the quantity of urea passed.

Before saying more about these charts I would venture to indicate how the personal factor has been carefully eliminated, since the observations on any particular day have been made by different individuals. Thus as part of the ordinary routine of work the staff nurse has recorded daily the amount of urine passed in 24 hours, and also the specific gravity of a mixed sample. This mixed sample has been daily examined in the pathological department, which has supplied a report showing the number of grains of glucose per ounce. From these data the daily amount of sugar has been calculated and recorded on the urine chart, while a separate chart prepared by the sister in the ward noted these results. Similarly the daily estimation of the urea and the weekly weight of the patient have been recorded.

In using sectional charts it was soon found that it was convenient to assign different values to the big squares. For example, if the amount of sugar was small it was better to assign a high value to each square, so as to keep the separate curves well apart from one another. We have usually kept to the same value for the urea and for the weight, but we have sometimes let each square represent either 100 or 200 grains of sugar. Therefore in considering any single chart it is important to remember the key which indicates the value of the square on that chart.

I lay some stress upon the number of hands through which these records passed. Those who tested and those who did the calculations before the records were entered had no knowledge of the changes that might have been made in the wards, either in diet or in treatment. I would also add that when we came to realise the value of these charts we endeavoured to avoid erroneous inferences by not making changes in the diet and in the treatment upon the same day.

In every case of glycosuria or diabetes it is common knowledge that patients may be restive and may surreptitiously obtain unauthorised starches and sugars. In keeping these records in hospital it is generally easy to trace any such departure from rules. Occasionally we are sufficiently fortunate to deal for long periods with absolutely trustworthy coöperation on the part of the patient, as well as on the part of all who have to make the records. In these comparatively rare cases a record that has been kept over a period of many months becomes of considerable value, and it is from such records that I have ventured to draw certain conclusions which I propose putting before the College to-day.

Before entering upon these conclusions it may be well to state that I do not propose to weary you with lengthy details of individual cases or with a formidable array of figures which might easily be drawn from my charts.

RELATIVE INFLUENCE OF DIET AND OF DRUGS.

Naturally one of the first features to claim attention was a comparison between the influence of diet and of various drugs upon the amount of glycosuria. This comparison is easy to make when the condition of patients on admission to the hospital permits two or three days to be devoted to a record of the daily output of sugar while on ordinary diet, and when they are sufficiently well also to permit a further short period to be spent in recording the changes which result from the gradual elimination of materials which would contribute to the formation of glucose. Under these circumstances we have found, in common with other observers, that an enormous reduction in sugar results during the first few days of the limited diet. In gouty, obese individuals of advanced age the sugar may entirely disappear under the influence of diet alone; this is especially noteworthy when the urine has been of comparatively low specific gravity and when there have been no urgent symptoms. In other cases we soon reach a stage beyond which it appears that no further benefit is to be expected from the ordinary hospital or hygienic surroundings, care, and limitation of starchy and saccharine material. In some cases, where patients previous to admission to the hospital have been treated as out-patients and dieting in their own homes, it has been necessary to combine dietetic and medicinal treatment immediately, and in these it has been difficult to determine to which form of treatment the rapid diminution of sugar was to be attributed.

On some occasions medicinal treatment has preceded any dietetic change, and the conclusions formed have been that such treatment without alteration of diet is of comparatively little value. Some reduction in the daily output of sugar has ensued during the first few days, but it has been difficult to avoid suspecting that this diminution might be the result of hospital management rather than of the remedies employed.

I do not propose to take up time by speaking of the relative value of different special or proprietary forms of diabetic food. I have used many varieties and have formed the opinion that to a large extent the taste of the individual has frequently to be consulted in the selection or the continued use of any particular variety of diabetic food or bread substitute. I have found repeatedly that after one form of food has been taken for a time and changed to another, the impetus of novelty will at first encourage the patient, even though there may be no important change to be recorded on the chart. On the other hand, where there has been marked distaste for the new form of food there has usually been an increase in the daily percentage of sugar, which has rendered it advisable to revert to the form originally well tolerated.

RELATIVE INFLUENCE OF VARIOUS DRUGS.

Directly we introduced the system of keeping records in graphic form, it was realised that the method was likely to be valuable in enabling us to trace the influence of drugs upon the amount of glycosuria. In these investigations it was obviously important to avoid being misled, either by the sensations or statements of the patient or by making changes of more than one factor at a time. For example, if possible we never changed the diet and the treatment simultaneously. Further, when a change of remedy was made we endeavoured to give the new remedy in a similar form to the one previously used—we might substitute one pill for another of different composition, or one mixture for another, but we did our best not to confuse the issue either by making too many changes at once or by placing reliance upon statements of improved sensations, which conceivably might be due to the sanguine expectations of a new mode of treatment. We sought cold impartial accuracy of result rather than the enthusiastic welcome of some new thing.

In the selection of the remedies employed we have been guided sometimes by theoretical considerations, sometimes by statements of the experience of other clinicians. Some of the remedies have been clearly used or recommended on an idea derived from physiological experiments, and therefore have some relation to the prevalent theory of glycosuria. Some have direct reference to the pancreatic theory, others appear to have connexion with digestive or other ferments, while of some the explanation is so elusive that they come under the banned (but useful) heading of empirical remedies. My desire has been to form an impartial opinion upon the value of the remedy in the individual case, and the conclusions must be taken merely as indicating that in that particular case certain remedies have or have not given satisfaction.

I do not propose to enumerate all the remedies that have been tried in my wards within the last few years, but to select for special mention only those where my charts indicate divergence from the observations of others, or where I have had reason to believe that benefit was directly due to the drugs. I have not found any remedy that can be considered universally applicable.

Codeine.

Codeine has been used in many cases, but in my hands the benefits, so far as sugar is concerned, have not been very obvious or constant. I do not deny that the records may sometimes have shown a certain reduction of the daily output of sugar during the time that codeine, or other derivative of opium, has been employed, and, while freely admitting that some patients appeared less troubled by thirst while taking codeine, and some were certainly less nervous and worried, I have occasionally feared that these drugs might be harmful. When the dose was increased from a third of a grain to half a grain I sometimes observed disquieting apathy and drowsiness, which led to a discontinuance of the drug. These symptoms may have been the direct result of the hypnotic influence of the codeine, or they may have been due to an arrest of the elimination of glucose, but in either case they were disquieting, as they resembled the usual forerunners of diabetic coma.

Sodium Salicylate and Sodium Bicarbonate.

My charts show that the use of sodium salicylate or of acetylsalicylic acid has given far more general satisfaction both in comparatively mild and in severe cases. When employing sodium salicylate in a case in which the glucose had been gradually reduced by dietary restrictions, we found that during the administration of the drug the glucose ultimately disappeared, and the benefit persisted even when a moderate amount of carbohydrate was allowed. For a short time any attempt to reduce the amount of salicylate while bread was being given was followed by a reappearance of glucose in the urine, but eventually it was found possible to allow two ounces of bread daily, even when the salicylate had been finally discontinued.

In collating my material I have found that I have made free use of large doses of sodium bicarbonate. This has in some cases been employed comparatively early, and it has been used to attempt to reduce the high degree of acidity which is so often present, even without any suspicion of acidosis. In my experience of hospital patients it has been extremely difficult to reduce this persistent acidity. Rarely, after very large doses, the urine has been rendered alkaline for a short time, but it has always speedily returned to a neutral or acid condition, in spite of the use of the bicarbonate.

I venture to lay some stress upon this observation, since most observers advise that, with the onset of toxic symptoms, indicated by drowsiness, severe headache, or coma, or by changes in chemical reaction showing the presence of acetone or diacetic acid, the urine should be rendered alkaline as quickly as possible. This is quite good advice, but it is not easy to obtain an alkaline reaction quickly, and it is still more difficult to maintain an alkaline or neutral condition of the urine for any length of time.

Guided by earlier experience I find that more recently I have frequently commenced medicinal treatment with a mixture of sodium salicylate and sodium bicarbonate, the quantity of bicarbonate being from twice to three times the amount of salicylate. The amount has been largely determined by the degree of acidity of the urine, or by the presence of drowsiness or other toxic symptoms.

Other Drugs.

When it has appeared that a stationary stage had been reached beyond which no further benefit seemed to result from modifications of dosage, while still continuing these remedies, I have given occasionally other drugs in turn, and have carefully noted the results. In one such case, which was under observation for many months, we were able to watch in turn the influence of codeine, takadiastase, and of trypsogen.

I have already referred to my general experience with codeine in connexion with other patients. In this particular case my chart showed that it exerted no material influence upon the output of glucose, while on the other hand the patient so often became dull and lethargic that it was deemed advisable to stop the administration.

In this case, and in others, I was similarly unable to confirm the favourable observations of others with regard to takadiastase. The reports made by Dr. E. J. G. Beardsley, of the Jefferson Medical College Hospital, were so striking that they merited investigation. He stated that takadiastase had a tendency to alleviate all the symptoms in diabetes. He said it decreased the amount of sugar for a time, but this finding was not constant. He asserted that, even while the sugar increased during the administration of the drug, the symptoms were relieved. He admitted, however, that the patients seemed more depressed for a few days following the first administration of the drug. From my observations I am inclined to agree with Dr. Beardsley so far as concerns the depression, but in my hands takadiastase has been connected with an increase of glucose, with no amelioration of other symptoms. I must admit that I have employed takadiastase in a relatively small number of cases, and therefore only say that in these particular patients the increase of glycosuria and the absence of any tangible improvement did not warrant a continuance of the treatment, and did not appear to justify further trial upon other patients.

With regard to trypsogen, my experience has been limited to its use on two patients. On the first occasion that it was employed the amount of sugar went up when three tablets were given three times a day. The use of trypsogen was continued for 19 days, when it was thought wise to leave it off as the amount of sugar still remained high. When it was discontinued the sugar went down to the merest trace, and later, the amount of sugar having again risen, trypsogen was given three times a day, with the result that the sugar rose with a huge bound, and after eight days it was again discontinued. I may add that on each occasion the patient objected strongly to the use of the drug.

It having been stated that calcium iodide very rapidly reduced the output of sugar in many cases, where neither dieting, nor the use of codeine had had much effect, I determined to test the value of this remedy in suitable cases. It was given twice daily in 5-grain doses to one patient for nine days. Before the administration he was passing 1520 grains of glucose in 24 hours, on the fourth day he passed 2000 grains, and the amount increased to 2440 grains on the ninth day, when it was thought advisable to discontinue. In a second case the same dose was given three times a day. At the commencement 1600 grains were being passed. After a week of treatment it was found that the sugar had increased to 2120 grains. In a third case 10 grains of calcium iodide were given three times a day. This was continued for 32 days, during which time curious oscillations of the sugar curve were observed. Starting from 1920 grains it fell in four days to 1480 grains. Then it rose with an oscillating line until it had reached a level of 2560 grains in another eight days. Then in five days it fell rapidly to 840 grains, after which, with fairly wide oscillations, it steadied at an average of 1600 grains. This experience of calcium iodide is confined to three cases, but since it entailed daily estimations over a period of seven weeks it is perhaps sufficient to cast some doubt upon the value of calcium iodide, and may serve to save others from similar disappointments.

Laxatives.

The importance of checking the tendency to constipation, which so often ensues with the restricted diet or results from the use of one of the derivatives of opium, has led to the frequent employment of laxatives. In glycosuria I have found that greater benefits follow from magnesium sulphate or sodium phosphate than from the vegetable purgatives. The salines in moderate doses have been given so frequently that it has been difficult to estimate any particular influence upon the output of sugar, although they certainly tend to a reduction of the acidity of the urine, to which reference has already been made.

Within the last few years additional interest has been directed to the use of massive doses of salines for the relief of urgent symptoms, and several cases have been recorded in which large doses of Hunyadi Janos water have checked symptoms of acidosis, and have been followed by a disappearance of acetone and diacetic acid. In the cases in which I have given Hunyadi Janos in this way I have noted two interesting facts. The first is that the degree of purgation is not proportionate to the dose employed; very large doses of the water seeming to be followed by no greater purgative action than might have been anticipated from a moderate or ordinary dose. The second fact concerns the output of sugar; in my cases I have found that there is a rapid fall in the 24 hours' quantity, and that, although on subsequent days the amount speedily rises, the level attained remains for many days far below the average observed before the use of this special treatment.

My experience, therefore, may be briefly summed up by saying that I have learnt to place reliance upon the use of some preparation of salicylic acid in conjunction with the frequent use of moderate doses of saline purgatives, or with the occasional employment of large doses of salines for two or three days in succession.

RELATION BETWEEN LOSS OF SUGAR AND WEIGHT.

With regard to the information the charts afford as to the relation of the loss of sugar and the weight of the patient, we have not found it necessary to make daily records of weight, since it is well known that slight oscillations of daily records of weight are of comparatively small importance. The weight has been taken at the same time of day once a week, and, in the majority of instances, the weight has been found to improve steadily with the reduction of the daily loss of sugar. We originally drew these two figures into comparison, so as to have some more definite indication of progress than the mere statement of the patient. It is obvious that the sense of well-being, although it may be expressed with perfect sincerity, is of small value as compared with a definite increase in the body weight.

This increase has been one of the most comforting features of many of my records, since it is an increase in spite of the elimination of many of the fat-forming articles of diet, and in spite of the reasonable amount of exercise which is permitted to these patients. The increase in weight, therefore, is not comparable to the increase in weight of tuberculous patients who are being kept recumbent and who are being fed largely with fat-forming materials.

The increase in weight is occasionally very remarkable. One of my most noteworthy examples is afforded by a man who had been treated originally in the surgical wards for a tuberculous testicle. When he first came under my care his weight was only 6 st. 7 lb. It rose almost continuously until, when he left the hospital, it had reached 10 st. This patient was again admitted to hospital towards the end of last November, his weight then being just 8 st. During the time that he remained with us, a little over two months, his weight again rose to 10 st.

I have learnt from continuous observation of these charts to attach relatively little importance to small oscillations in the amount of sugar, so long as the line marking the weight shows a steady rise. The converse, unhappily, holds good. When the amount of sugar has been gradually reduced, either by diet or by drugs, if there is a rapid loss of weight, the case cannot be regarded as satisfactory, and I have felt justified in administering articles of diet which would increase the amount of sugar provided that they also caused an increase in the weight. In many chronic cases my charts confirm the common experience that it is wise to permit some carbohydrates to maintain the weight and well-being of the patient.

In this connexion I would mention that these observations have relation only to the question of the weight and the sugar. They are not influenced by any other considerations, such as an increase in the reactions for acetone or diacetic acid, or by any symptoms of acetonæmia.

RELATION BETWEEN LOSS OF SUGAR AND UREA.

Having a chart on which it was possible to represent the daily amount of urea in addition to the other factors, and having many willing workers ready to assist with the daily estimations and calculations required, we have in recent years recorded the daily output of urea in all our cases of glycosuria. It was hoped that in this way we might be able to confirm from a clinical side the statement of Graham Lusk on the dextrose: nitrogen ratio, which in phloridzin diabetes, after all carbohydrates in the body, such as glycogen, have been got rid of, was placed by him as a constant ratio—viz., 3·65 : 1. It has been found convenient to express urea in terms of percentage rather than to attempt to calculate the actual amount of urea passed daily. To some extent, therefore, during the earlier phases of each of the charts it is not fair to attempt to compare the percentage, which takes no note of the quantity of liquid passed, with the figure for glucose, which is an actual amount calculated in relation to the quantity of urine eliminated. During the later stages—that is, after the case has been under observation for a fortnight—the daily amount of urine passed usually varies within a very small range, and it now becomes possible to obtain an idea of the relation which may exist between the dextrose and the nitrogenous output.

I am aware that the estimation of urea will not include all the nitrogen to be found in the urine. There are numerous other compounds of nitrogen which should, perhaps, be taken into account before attempting to draw conclusions. Urea, however, represents such a large proportion of the daily nitrogenous loss that it may be assumed that the dextrose: nitrogen ratio above mentioned should be maintained even as regards urea; in other words, it might be expected, from experimental data, that when we are dealing with a large number of daily records we should find some relation between the output of glucose and that of urea. We might anticipate that an oscillation of the dextrose line should be accompanied by a proportionate oscillation in the same direction of the urea record.

Upon this point I must confess that our expectations have not received any support. Viewed alone the urea curve has certainly shown many variations from day to day; usually these are within a very moderate range, but occasionally there is a sudden considerable rise or fall of the urea curve. We have found that this appears to have no relation to the dextrose line, which in its turn may betray similar instability without any change in the general trend of the urea curve. At present no explanation is forthcoming for these oscillations in the urea curve.

I can only state that prolonged observations have shaken my faith in the clinical value of a comparison of the dextrose urea curves. Changes in the amount of urea, so far as my experience extends, do not appear to have any clinical or practical bearing upon the course of the glycosuria or diabetes. They are probably the result of some change in the diet or of some difference in the amount of exercise, but they do not occur with sufficient regularity to throw any light upon the prognosis, and, on the other hand, they are too frequent for it to be assumed that they are due to experimental error.

THE CHARTS AND PROGNOSIS.

The amount of patient labour entailed in the construction of the graphic records of cases of glycosuria and diabetes led me to attempt to derive the utmost information from them. Naturally in every case the prognosis is an early question, and in this it was hoped the charts might help materially. Hitherto the prognosis has been guided by numerous well-known factors—for example, the age of the patient, the specific gravity of the urine, the degree of emaciation, the occurrence of toxic symptoms like drowsiness, or that curious feature of air hunger, or the development of grave complications like carbuncles, boils, or gangrene, which so often have been regarded as leading on to a fatal termination.

Our charts helped in forming a prognosis in various ways. They showed the relative influence of dietetic and medicinal treatment, and left no doubt about the greater importance of diet.

They enabled us to test the amount of improvement resulting from various drugs, and helped us to draw conclusions which, however, had to be guarded, conclusions limited to the statement that in the particular case certain drugs had or had not given encouragement for further guidance. Our graphic records led us to speak with reserve on the prognostic value of a daily estimation of urea, and with still greater hesitation on an attempted comparison of the output of urea and of sugar. Most important information, however, was derived from the comparison of the curves showing the relation between the loss of sugar and the gain of weight. In true diabetes we learnt that a steady increase of weight, in spite of a moderate amount of sugar, had to be regarded as a favourable element in the prognosis. In the absence of toxic symptoms, anxiety was only felt when there was a rapid decrease of weight, in spite of measures taken to limit the loss of sugar. No anxiety was felt when in elderly obese individuals there was a steady loss of weight together with a rapid diminution of sugar.

We had, indeed, gone far towards feeling that our records would contribute largely to the available information for framing a prognosis, and then came a check which for the time seemed likely to upset all our confidence.

Cases with Suppuration or Gangrene.

Soon after the graphic charts were in use several patients were transferred from the surgical to the medical wards on account of glycosuria. Some began with symptoms which led us at first to fear we were dealing with advanced diabetes. The thirst, the amount of urine, the high specific gravity, and the rapid emaciation appeared to warrant a serious diagnosis. Then after an interval of treatment the symptoms improved and the serious aspect disappeared, and we had to revise our early diagnosis.

These cases all had either some form of suppuration or some form of gangrene, and the patients were sent to the medical side owing to the fear of performing operations of any magnitude while sugar was present in large quantity. Generally the gangrenous part was dressed with boric acid, or in cases of suppuration incisions were made to afford free escape of pus. I repeat that most of these patients on admission presented every indication of severe diabetes, and yet the sequel showed that this diagnosis was not correct. The improvement of the glycosuria was too rapid and, I may add, too unexpected to be attributed either to the modified diet or to the remedies employed. The symptoms had been too grave to warrant an assumption of a dietetic glycosuria, and some other explanation had to be sought. The current theory that "with the onset of severe complications the tolerance of the carbohydrates is much increased" seemed to offer a suggestion, but it was difficult to believe that severe complications like boils, carbuncles, perforating ulcers, or gangrene could lead to a tolerance of carbohydrates which should produce not only a disappearance of sugar, but also a rapid amelioration of all symptoms commonly associated with serious glycosuria.

Since our graphic records demonstrated facts which were so unexpected, it was necessary to look more closely into the clinical features of these cases and to attempt to discover some common factor. I have selected the following brief notes to show the nature of my experience of some cases of perforating ulcer or of gangrene with glycosuria.

A woman, aged 50, was admitted complaining of bad feet and great thirst. The increased thirst had first been noticed three years before, but had passed off until a fortnight before admission. During the last two years there had been gradual loss of weight. She stated that one year ago a nail had run into her foot and caused a wound, which first healed up and later broke down again. There was a sinus near the ball of the great toe which was enlarged and dressed; later the first metatarso-phalangeal joint was excised. On admission the urine had a specific gravity of 1030, and contained much sugar (28 grains to the ounce). Under dietetic treatment the amount of sugar speedily diminished, and after the operation sugar disappeared entirely.

A second case was somewhat similar, but there was no history of injury. This patient was also a woman, aged 43. She stated that some years earlier she had had an ulcer on the right foot, which, although under treatment, had taken three years to heal. Trouble in the left foot began with an ulcer in the sole ten months before admission, and within two months three other ulcers appeared. During this time there was rapid loss of weight (from 16 st. to 10½ st.), great thirst, frequency of micturition, and marked constipation. The four ulcers were connected by deep sinuses, and there was much offensive discharge. Under stovaine the openings were enlarged, and boric fomentations were used. The healing process was slow, four months elapsing before the ulcers closed. On admission the urine contained 21 grains of sugar to the ounce. During treatment sugar was speedily reduced and was often entirely absent.

A third case showed perforating ulcer, followed by gangrene, in a man over 60 with chronic interstitial nephritis and glycosuria. There was a history of chronic alcoholic excess, and the condition was so bad that the prognosis appeared desperate. Treatment with boric fomentations, and the removal of necrosed tissues were followed by rapid improvement and a reduction of the sugar. A year later I heard that the foot had healed, and that sugar was no longer to be detected.

A still more striking example was afforded by a patient whom I saw in consultation with a surgeon about three years ago. The patient was a man, aged 53, suffering from gangrenous phimosis, and the surgeon was averse to operation owing to the presence of sugar in the urine. The history showed that during two years there had been increasing frequency of micturition and some loss of weight. Four days before the patient saw me he had been markedly drowsy and had complained of parched mouth and dry tongue. Although the specific gravity when first examined was 1040, it speedily fell after the removal of large gangrenous sloughs, and within a month it was extremely difficult to obtain any reaction for sugar. The sugar ultimately disappeared until the patient had an attack of tonsillitis, when during the high temperature sugar was again found to be present for a short time.

Relation of Glycosuria to Gangrene.

These cases led me to go through my earlier records of other forms of gangrenous conditions, and to study again the literature of this subject. I found that my own notes showed that in gangrene, and in perforating ulcer of the foot, associated with glycosuria, there has invariably been a marked diminution of sugar during the treatment of the local condition. As the improvement was more rapid and more complete than that resulting from dietetic or medicinal treatment, it seemed possible that the common factor we were seeking might be found in the removal of some hitherto unsuspected cause for the appearance of glucose. Again, it has been noted by others that with a return of gangrene there has been a fresh glycosuria. In one such case the glycosuria and gangrene have returned on three separate occasions.

During the last few years there has been an increasing distrust of the accuracy of the term *diabetic gangrene.* Many observers, surgeons, have maintained that the gangrenous change results from arterio-sclerosis with thrombosis, rather than from a primary local infection favoured by the presence of sugar in the circulation, as was formerly supposed. This view would suggest that we are really in such cases dealing with senile gangrene occurring in patients who are unfortunately suffering from diabetes, which of necessity presents a grave additional risk. While it must be admitted that in such cases the process of healing is extremely slow, I believe this may be due to defective circulation, the essential cause of the gangrene, and not to alterations in the composition of the blood associated with glycosuria. I think this view should encourage greater readiness to remove gangrenous tissues at an early stage. Operations of greater magnitude might well be reserved until the quick reduction of sugar has permitted greater liberality of diet.

Hitherto there has been, so far as I can trace, no suggestion that the glycosuria may possibly be a feature which has arisen subsequently to or concurrently with the gangrenous process. When once this idea presented itself I again went through my notes and was surprised to find how frequently patients had made mention of some suppurative process shortly before the onset of the symptoms which are definitely referable to a pronounced glycosuria. One dated his illness from an abscess in the jaw, several had mentioned dental troubles, and repeatedly came the statement of serious pyorrhœa, a statement made by clinical clerks, when there had been no thought of the possible future value of the recorded fact.

CONCLUSIONS.

We have learnt the value of early relief of pent-up pus, of early removal of gangrenous tissues, and of the adoption of measures to prevent septic absorption. Can we not go a step further and add yet another theory for glycosuria which may knit together in a new light the results of clinical observation, of physiological experiments, and of pathological investigations?

While greater influence on glycosuria is exerted by diet rather than by drugs, the remedies which have proved most efficacious, the salicylates, are those which we ordinarily credit with the power of controlling toxic processes resulting from the growth of micro-organisms. From the experimental side glycosuria has been induced in dogs by injecting into the pancreas irritants which have produced pancreatitis or extensive sloughs. By the removal of sloughing tissues, as in carbuncles, in perforating ulcers, and in gangrene, we find clinically that glycosuria is quickly reduced. Do not these observations, collectively, warrant the suggestion that some cases of glycosuria depend upon a perversion of pancreatic secretion due to toxic absorption? If this view is correct, may it not also lead to the employment of a vaccine to counteract the toxic influence?

To return to my graphic records, if they contribute to a more sanguine view of the value of early treatment, and if they lead to a new suggestion for future workers, all concerned in the labour will be amply repaid for the trouble involved in lengthy observations carried out with no preconceived idea of the results which might be attained. My graphic records are the result of patient and cordial coöperation of the pathological department at King's College Hospital, and of many ward sisters, nurses, house physicians, and clinical clerks. To them I once more tender grateful thanks for loyal service, and to you, Sir, I venture to express my gratitude for this opportunity of giving publicity to their work.

SOME OF THE PROBLEMS OF GUNSHOT FRACTURES.

By ERNEST W. HEY GROVES, M.S. LOND., F.R.C.S. ENG.,

CAPTAIN, R.A.M.C. (T.F.); SURGEON TO THE BRISTOL GENERAL HOSPITAL AND LECTURER ON SURGERY IN THE UNIVERSITY OF BRISTOL.

Frequency.—It is difficult to over-estimate the importance of the timely solution of the many problems connected with gunshot fractures. The severe injuries of other kinds—e.g., penetrating wounds of the head or abdomen—are mostly fatal, and it is probable that the cases of shattered long bones constitute the largest single group of serious non-fatal wounds. And not only do these cases survive, but their after-condition will depend very largely upon the way in which the injury was treated in the first place.

Pain.—Again, there seems almost no limit to the pain which may be caused by these bone injuries, both by mobility and by sepsis. The first, and perhaps from the humanitarian point of view most pressing, question is how to treat them at each stage so as to mitigate this suffering. The pain is not only so severe, but in the femur it is of such long duration that a man may have to suffer for several weeks daily agony when his wounds are dressed. The amount of pain will depend upon the degree of the injury, upon the occurrence of sepsis, and also upon the necessity for movement. The first two factors are largely out of our control, but the last is one which is insistent for solution. The limb must be immobilised for transport and also for the constant change of dressings. It is this latter point which is so difficult to carry out efficiently.

Sepsis.—The horrors of the worst types of sepsis associated with open bone fractures are familiar to all who are attending upon the wounded. The simple pyogenic sepsis, the gas gangrene and pyæmia are of frequent occurrence, and serve not only to make the injury more difficult to treat but render it a serious menace to life and limb. And after the first danger to life is over and the limb appears to be saved, the septic complications remain for weeks and months, requiring elaborate dressings and weakening the patient by the constant drain upon his strength. A further evil of septic infection lies in the loss of tissue, especially of the bones, which it causes. A septic process energetically treated may be cut short, with but little loss to the limb; but, allowed to spread, it may destroy a large part of the bone. The treatment of these septic limbs is difficult, requiring the utmost judgment and resource. Mere drainage by the insertion of rubber tubes appears to be quite inadequate. This device, which we have learned to rely upon in the sepsis of the serous cavities or in the treatment of a localised abscess, quite fails us in a septic limb. The septic process seems to spread so readily in the loose connective tissue planes between the muscles that the mere provision of an outlet does not check it. The limb must be widely opened up, foreign bodies, such as bullets, pieces of shell, loose bone fragments, and pieces of clothing, removed, and the large wound packed with gauze after swabbing with iodine. In some cases the provision of constant irrigation at an early period will probably cut short a spreading inflammation, but in all severe cases the tissues must be opened up freely.

The problem of life or limb?—We know that by adequate means we can often save a useful limb by conservative surgery which an older generation would have immediately sacrificed. But this conservation entails a grave responsibility. For in the attempt to save the limb we may lose the life. No rule can be laid down which will avoid this danger, but one general principle must guide us. It is that the combating of sepsis must be carried out in the most energetic way from the outset; the limb must be mutilated to be saved. Large bones and joints which are the seat of septic infection must be freely exposed and no attempt made to sew up the soft parts. This will lessen the danger to life for the moment; if successful, the limb will be less mutilated by incisions than by unchecked sepsis; and if, after all, the limb has to be sacrificed the ultimate amputation is less severe.

The function of the limb.—In the urgent problem of saving the vitality of a limb certain minor points relating to the preservation of its functions must not be lost sight of. These are the restoration of the bone to its natural length and line, the preservation of the nutrition of the muscles and the mobility of the joints. I call these minor points, inasmuch as their observation must in no way interfere with the prime necessity of combating sepsis, but later they are of major importance, because they determine how much use the limb will be after it has been saved. By the observation of three principles the condition of the limb may be secured very largely in all these respects. These three principles are those of constant extension, the semi-flexed position of the joints, and the use of apparatus which does not immobilise the joints above and below the broken bone.

The use of apparatus.—The use of all kinds of splints, slings, and apparatus requires the most careful consideration. A splint may be the greatest blessing or the greatest curse, according to whether it is properly adapted and intelligently used or otherwise. For military purposes the apparatus must be of the simplest and cheapest kind possible, so that it can be quickly made by local workmen. It must be capable of adaptation to the varying circumstances of the hospital, so that any bed can be fitted with it; and, above all, it must be adaptable to the needs of each case, so that the apparatus can be suited to the fracture and not the fracture to the apparatus. If possible, it ought not to require a long process for its application, neither ought it to need constant readjustment. I believe that the methods introduced by Florschütz, Borchgrevink, and von Saar, which were described in THE LANCET of Sept. 26th and Oct. 3rd and 10th, 1914, by Mr. J. H. Watson and Dr. T. Snowball, constitute by far the most efficient means at our disposal as yet described of carrying out these principles. Dr. von Saar was kind enough to lend me specimens of these splints, &c., for my recent Hunterian lecture,[1] and I have since put them into use and modified them to some extent. The descriptions and figures given in the article referred to will obviate the necessity of further details, and I will confine myself generally to points of principle and to an account of additions and modifications which I have used.

The rôle of extension.—No one doubts that for the treatment of fractures of an ordinary kind extension is the most important principle. But it must be borne in mind that in cases of gunshot wound with severe sepsis the treatment of the sepsis must take precedence over the restitution of the bone form. Now in extension the muscles are made taut, and close in round the bone, and the fragments of bone come to lie end to end. This hinders drainage. It is better, therefore, to recognise that there are three stages in the treatment of all these septic cases: (1) The cure of sepsis in which freedom of drainage and absence of tension are the most important factors; (2) the healing of the bone, which must be placed in good position by extension; and (3) the restoration of function to the joints and muscles by early movements. If this be accepted, then, it is wrong to adopt extension in the early stages of sepsis, or until free drainage has been assured. Not only must the wounds be enlarged, but in order to prevent the muscles falling together they ought to be incised transversely. This will secure a widely gaping wound and will lessen the overlapping of the bones. The time for extension to be begun in septic cases is when granulations appear. This indicates healing, and up to this time no bone repair occurs, and therefore it is a matter of no consequence whether the bone fragments overlap or not. Indeed, it is often the wisest thing to do to intentionally angulate the bone at the seat of fracture, so that its ends may lie superficially in the wound, and this position can easily be rectified when the tissues are clean and any dead bone has been thrown off.

Arm fractures.—Borchgrevinck's splints are excellent. That for the humerus consists in a Y and that for the forearm in an L-shaped piece of wood provided with a pulley at the distal ends; in both extension is provided for by a loop of rubber tubing. I have used instead of the latter the solid rubber doorspring which costs only 1*d.* and gives an extension up to 8 lb. But for elbow fractures it is better to use an internal angular splint with the corner cut out for drainage and a piece of wood which lies in front of the biceps as counter extension. For shattered forearms I have used a simple metal framework jointed on to an arm-piece. This allows movement at the elbow and also free rotation of the hand and free access to the wounds. In the shoulder fractures the great difficulty is stiffness in a position of adduction, and to overcome this the arm ought at an early period when the wounds have cleaned to be placed above the head; at first an anæsthetic is necessary for this and later the position of extreme abduction ought to be maintained for 12 hours each day when the patient is lying in bed.

Fractures of the femur.—These cases constitute some of the most difficult and the heaviest of all the serious wounds. They cannot be easily transported, they require elaborate dressing daily or twice a day, and they take weeks or months to heal. Florschütz used the method of suspension of the leg in a semiflexed position, with a weight extension, in the Balkan war, and the method is most excellent. The leg is slung to a bar running above the bed in its length by three slings and an adhesive plaster attachment holds the extending weight. This method, however, requires some time for its application, and as it depends upon continuous extension is liable to objection in the early stages of open fractures with severe sepsis. It is far better by reason of its simplicity than the Hodgen's splint, which is only good when perfectly adjusted and strongly extended. I am sure the Hodgen's splint is quite unsuitable for cases which require constant dressing. For the transport of cases of fractured femur nothing is better than the French wire cradle, which is both firm and light and effectually prevents rolling. The long Liston splint is a very poor protection against mobility and requires to be well applied, whereas the cradle splint holds the leg by its mere shape. The most generally useful splint for open thigh and leg fractures in their early stages is, I believe, an angled trough which supports the leg in a semi-flexed position. The thigh part must either be a separate structure or else readily taken off from the leg-piece, so as to allow for dressing and irrigation. The main principle is to support the leg by a trough under the calf at a height of about 8 inches from the bed. The thigh is then prevented from sagging by another splint or by a suitable pillow. Such a device can be made quickly by any carpenter, and when made its adjustment is done in a few moments. For dressing the thigh the upper splint or pillow is removed with the minimum of disturbance. When sepsis is lessened and the granulations appear a sling extension can be substituted.

The treatment of clean leg fractures with much shortening or comminution.—If the case is clean from the outset or when active sepsis is at an end, there may be great difficulty in restoring the length and shape of the bone. For a long time it has been demonstrated that by transfixing the lower bone fragment by a stout steel rod effective and correct traction can be made which will rectify the displacement. But this necessitates four to six weeks in bed. By transfixing the upper and the lower fragments a perfect restitution of the bone can be made under an anæsthetic by means of external extension screw bars, and the patient need not be kept in bed. Until recently I believed that this could only be used for the lower leg bones where both transfixion pins can be placed parallel to one another across the bone. But now I have completed a quite simple device which extends this principle to the femur or humerus, and in which the upper transfixion pins are antero-posterior, whilst the lower runs from side to side. In the femur this upper pin goes through the base of the great trochanter and the lower through the condyles. I will postpone a detailed description of this apparatus until I can give the results of its use.

---

[1] THE LANCET, Feb. 14th (p. 435) and 21st (p. 513), 1914.

The wrong principles of treatment of septic open fractures.—As a last word, a warning may be uttered about errors of treatment which it might be thought would never be committed, but which nevertheless are of comparatively common occurrence. 1. To sew up a gunshot wound or laceration is wrong. Such treatment will often produce the most malignant type of sepsis or gangrene. 2. To attempt to suture or plate the bones is wrong. It necessitates wide incisions and endangers life, whilst it cannot achieve its purpose. The first principle for septic bone injuries must be to open up and not to close the wounds both of the soft parts and the bones. 3. To put up limbs in plaster is unjustifiable at an early stage, when the degree of sepsis is unknown. It causes pain, a retention of septic discharges, and endangers both life and limb. In exceptional cases plaster may be justified as a means of ensuring immobilisation during transport; but then the plaster should be light, with strengthening pieces of wooden lath or zinc. It should be put on in such a way that it can quickly be cut off—e.g., by leaving strings in front and behind for the introduction of wire saws or by placing a metal strip along and below the lines of the saw cuts between the dressing and the plaster—and most important of all, there should be a peremptory note written on the plaster case saying that it is to be removed within 24 hours of such and such a time.

Clifton, Bristol.

THE INCIDENCE OF PLAGUE IN EUROPE,

WITH SPECIAL REFERENCE TO THE RÔLE PLAYED BY THE RAT.

BY C. STRICKLAND, M.A., B.C. CANTAB.,
TRAVELLING MEDICAL ENTOMOLOGIST, FEDERATED MALAY STATES.
(*From the Malaria Bureau, Kuala Lumpur, F.M.S.*)

Madam Frances Pitt, writing in the *National Review*, says that plague has now no potential incidence in Europe, this not only being proved by the experience of the last centuries, but by the fact that the brown rat, which only carries a "large northern flea" incapable of feeding on man, has replaced the black rat, which, on the other hand, carries a flea an avid feeder on man.

Now in this paper it is hoped to prove also with Madam Pitt that plague has no further potential epidemic incidence in Europe, and for the same reason—to wit, that the brown rat has replaced the black. But before going any further I would venture to disagree with her induction concerning the flea. The large "northern" flea mentioned must surely be *Ceratophyllus fasciatus*, while the flea of the black rat meant is probably *Xenopsylla cheopis*, but it is a fallacy to suppose that the former bites not man—in fact, we here have found by experiment (1913) that it seems actually to be attracted to man rather than to the rat; and as for *cheopis*, which is responsible for plague in India, it is unusual to find it in northern climes—an only exceptional occurrence having been recorded from a place in London, where it was found breeding under some hot water pipes. The fleas of both species of rat in this country are identical, and if the brown rat by replacing the black has caused the disappearance of plague, it is not because the fleas which he carries are different.

We must look for other reasons to account for the disappearance of the plague. That it has been coincident with the change in the rat fauna, which is stated to have occurred in England, is certainly borne out by the experience of the last centuries, and we have as a control the fact that in seaboard towns such as Amsterdam, which still are infested by the black rat, plague does occur in outbreaks. This evidence so far certainly goes to prove that the rat factor is the cause of the change.

Now how should the brown rat make any difference to the incidence of plague if the black rat was responsible for it in former times? They are both rats, and have identical fleas. The whole answer to this question is bound up in our knowledge of the different habits of the two species. In the first place the black rat, as pointed out by the Indian Plague Commission, is a semi-domesticated species, it does not fear man, the consequence of which being that should it suffer from plague its fleas are within easy reach of man, whose rooms he inhabits. On the other hand, the brown rat is a savage, wild creature, fearing man and shunning his society; consequently, should he suffer from plague he probably distributes his fleas as far from man as he would like to be himself. He lives in the foundation of the house if he live there at all. As a matter of fact, he only lives near human habitations for a half of the year, for which reason he is just half the danger to man that he would be if he lived near him for the whole year—he hies him forth in the glad summertime to the country-side in search of food and makes his burrows in the hedgerows and fields. Another difference between the two species is that the black rat staying at home in the summer time does not fear the great centres of human population; the brown rat, on the other hand, being essentially a country-side rat, and only coming near a human habitation when he cannot get food in the fields, is therefore to be found in greater numbers in the smaller aggregations of human dwellings; he is first a farmyard rat, then a village rat, then a country-town rat, but he is not easy to find in the big towns. Consequently, should the black rat suffer from an epizootic of plague he will produce, owing to the density of the human population, a frightful epidemic, as he does now in India; and as we are told he did in England before the brown rat killed him. While, on the other hand, the brown rat living in more scantily populated districts will not cause an epidemic, other things being equal.

These hypotheses are borne out by actual facts. In India we have the semi-domesticated black rat living in the midst of a teeming population; it suffers from an epizootic of plague measuring 8 per cent., and the whole of the human population is devastated by the disease (see the Indian Plague Commission's report). In a small parish in East Anglia the brown rat was suffering from "a raging epizootic" of 11 per cent., and the human population was in that parish unaffected. The brown rat does make a difference, because he keeps away from the great centres of population. On the contrary, that *Mus decumanus* is a danger if he is living in dense centres of population is proved by the case of Shanghai. Here we are told that *M. decumanus* frequents the squalid surroundings of the native town, and is the cause of much plague.

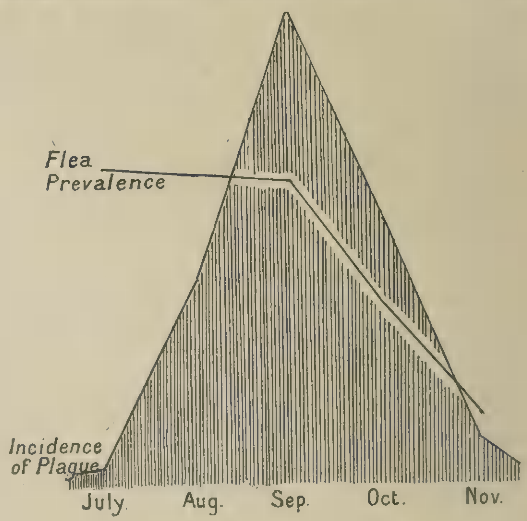
That habit of the brown rat mentioned above—that of wandering abroad in summer in search of food—has the effect, as has been said—(1) of taking him further from human beings and so lessening the chances of infection; and (2) of taking him to the midst of even less dense populations than he is near to in the winter. But it has another effect which lessens still more the chances of infection of human beings, weakening, as it does, one of the links in the chain of causation of the disease, and that is, he is less liable to suffer from plague himself. He disperses over the country-side, and with every yard which he places between himself and the focus of infection he lessens the chances of becoming infected himself by $\frac{\pi r^2.}{2}$ Here, again, the factor of density of a susceptible population comes into play. We have actual figures in support of this. In a certain parish in East Anglia Martin and Rowland (1911) found an epizootic among the rats of 11 per cent. This was in the winter when the flea-rate per rat was 1. Now the flea-rate per rat in summer goes up to 4·5 (Strickland and Merriman, 1911), but the epizootic in the rat does not obtain any greater dimensions in spite of the increased flea-rate, as we would expect from the Indian Plague Commission's reports. Certainly in India the infection-rate is directly proportional to the flea-rate in the rat, but it is not so here, where the brown rat is involved. Far from it, in East Anglia the infection-rate of rats in the summer, 1911, was 30/15,000 = 0·2 per cent. So in spite of the flea-factor being 4·5/1 stronger in summer than in winter, yet the adverse factor, which we take to be the lessened density of the rat population in summer, was so powerful that the epizootic resulting was 0·2/11 or 1/55; that is, the dispersal of the rats in summer lessened their chances of infection by nearly 250 times. And if the rats' chance of infection is 250 times less in summer than in winter, the chance of human infection decreases *pari passu*.

This, therefore, is a distinct difference to the black rat. Whatever the chances of epidemics are now, they are certainly the greater in winter, and Manaud's (1911) statement that plague has a potential incidence in summer now does not seem to us correct. We think that he has overlooked the rat factor.

This fact in connexion with the brown rat seems to us to be evidence that the brown rat if it existed in Europe in the days of the great epidemics never was a factor in the causation of the disease. If it had been we would have records of winter epidemics, but we have not. The danger from plague now lies chiefly in winter, if at all, and all the more so because in a rigorous climate a few sporadic cases due to flea infection might develop into a pneumonic epidemic, as it did in Manchuria lately.

We are told that the brown rat overcame the black rat when it was imported into England after the Great Plague of London. Up to that time, then, the black rat had been solely responsible for the epidemics of plague, and the records show that it was a summer disease or coincident with the period of greatest flea prevalence, which is in summer, as Mr. Merriman and I have shown (1911). (See Chart, also Manaud, 1912.) Now we think it probable, knowing the habits of the rats, that the brown rat did not vanquish the black rat. What caused the disappearance of the black rat, we think, was better housing, and he would have disappeared whether the brown rat were in the country or no. Compare the state of affairs in Java nowadays (Swellengrebel, 1913): there the brown rat has established himself in small numbers on the coast, where are the European establishments; inland it obtains no further holding, for the native houses of bamboo and attap (thatch) are not to its liking. If indeed the brown rat *per se* has overcome the black rat, why not introduce him into Bombay or other plague-stricken centres? If he overcame the black rat once in England, what should prevent him doing it in Bombay? It was better housing which caused the disappearance of *Mus rattus*, and that should be borne in mind in localities where the black rat still persists.

To our mind, probably *M. decumanus* was in the country prior to the Great Plague of London, and as the conditions then were probably somewhat similar to Shanghai native town nowadays, it is possible that he too was responsible for some of the plague then. If he were not in the country then, it only means that the conditions which were unfavourable to the black rat were favourable to him—foundations to houses, sewers, &c., and also the planting of hedgerows which became the vogue just then, as Madam Pitt points out, owing to the scarcity of farm hands. It was not that *decumanus* vanquished *rattus*.



For prevention then it seems very important that the black rat should be eradicated, and this it seems is best done by replacing wooden structures by stone or brick ones. As for the brown rat, he will probably keep himself away from human populations in the summertime; in the winter it must be remembered that all access to food supplies must be denied to him. Paved streets and concrete basements will probably always keep him away, and are therefore an advantage. In suburbs and the outskirts of country towns, and in country villages and hamlets, ferreting and trapping should be carried out *in the winter*, and viruses may be laid then. We cannot hope to reduce the flea-rate of the rat. Baldwin-Latham proves that this is correlated with the vaporous exhalations of the ground. Strickland and Merriman found no close connexion between it and the temperature.

Conclusions.—1. The black rat was responsible for the great plagues of Europe in the past. The epidemics had a summer incidence due to the increased flea prevalence at that season. 2. When good housing became the vogue the black rat disappeared. The brown rat did not vanquish him. 3. At the same time the brown rat increased owing to the introduction of conditions which suited him. 4. He has not proved a factor of any importance in the epidemiology of plague, because—(i.) his shyness of man takes him as far as possible from man and decreases the chances of infecting him; (ii.) his shyness takes him away from the greater centres of population, where it would be easier to start an epidemic—he is essentially a country-side rat; and (iii.) in the summer the fact that he is dispersed over the country-side in search of food lessens the probability of an epizootic among his species by, we calculate, 250 times. This fact also shows that whatever danger he creates is accentuated in the winter, which proves that he was not responsible for any of the epidemics of the past, occurring as they did in summer. It also shows us that the best and most useful time of the year to attack him is in the winter. 5. Measures directed against the black rat should be the replacement of wooden by stone structures; against the brown, no access to food-supplies, street paving and concrete basements; ferreting, trapping, and viruses in the winter; good houses instead of rows of "jerry-built" structures. In general we conclude that plague has no further potential epidemic incidence in Europe, wherever the brown rat has replaced the black

OCULO-MOTOR PARALYSIS OF OTITIC ORIGIN.*

BY F. H. WESTMACOTT, F.R.C.S. ENG., B.SC. VICT., &C.,
HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY;
HONORARY CONSULTING AURAL SURGEON, MANCHESTER
CHILDREN'S HOSPITAL, AND ST. JOHN'S HOSPITAL
FOR THE EAR, MANCHESTER.

INTERFERENCE with the function of the third cranial nerve may occur in one of three parts, according to the symptoms produced. Firstly, in the nuclei of origin in the grey column in front of the aqueductus cerebri and the corpora quadrigemina, together with the supranuclear portion. Secondly, in that portion which extends from the point of exit of the united bundle of fibres on the medial side of the cerebral peduncle, just in front of the pons, passing forwards between the posterior cerebral and superior cerebellar arteries to pierce the dura mater beside the posterior clinoid process; in the small triangular space between the free and attached borders of the tentorium cerebelli. Beneath the dura mater the nerve courses through the lateral wall of the cavernous sinus until it enters the orbit through the superior orbital fissure. Thirdly, from its entrance into the supra-orbital fissure and orbit, where it divides, to the terminations of its distribution. It is considered, however, that all lesions below the nuclei are peripheral, all above are cerebral. Landolt classifies all peripheral lesions as orbital (including supra-orbital fissure), basilar, and fascicular, the cerebral as subcortical and cortical.

It is with the second division, or basilar, that the otogenic lesions are intimately concerned, but it is also in this portion that the rhinogenic diseases affect the nerve trunk. It is necessary that some account must be taken of the latter, as well as the concomitant affection of the other oculo-orbital nerve trunks, in order to discuss the differential diagnosis of paralysis induced by disease of the auditory organ in the temporal bone from that originating in neighbouring parts. The number of otogenic and rhinogenic lesions of the oculo-orbital nerves which have been published is small, but of those the latter are numerous and the former rare.

It is necessary to recall the anatomical relationships of the oculo-orbital nerves to the temporal bone to appreciate the pathological changes which may affect each nerve. All the nerves are situated near the apex of the petrous portion, and well out of the way of disease limited to the organ of hearing, but extension of disease by bone or soft parts will have different results. The largest area of contact is that of the trigeminus, which lies in a depression on the anterior and superior surface of the apical region of the petrous bone. The Gasserian ganglion and the three divisions of the fifth nerve are held in position by the dura mater, which is divided and forms the cave of Meckel, the inferior portion forming the periosteal covering of the Gasserian impression, while the upper is closely connected with the tentorium cerebelli and with the dura of the cavernous sinus and the dorsum sellæ.

The next most extensive relation, appearing at the pyramid and posterior border of the pons, is the abducens, which pierces the dura mater in the posterior fossa postero-laterally to the dorsum sellæ, entering the cavernous sinus medial to the fifth nerve to reach the superior orbital fissure, on a lower level and deeper than the oculo-motor. It is in immediate proximity to the petro-occipital suture, the inferior petrosal sinus, and the apex for a distance of about 3 cm. Dorello describes a narrow cleft in which the abducens runs along with the inferior petrosal sinus, and is firmly bound down to the apex of the pyramid by connective tissue and dura as well as the petrosphenoidal ligament. The fourth nerve passes into the dura and cavernous sinus at the anterior attachment of the tentorium cerebelli, just above and to the inner side of the trigeminal nerve, but external to and above the abducens. It lies inferior also and enters some distance behind the oculo-motor.

The oculo-motor nerve is relative to the temporal bone in the second of the divisions described above—namely, the extradural portion and its continuity through the external wall of the cavernous sinus, being separated from it posteriorly by a thin membrane, whilst in front it lies in the blood stream. It is, however, the most distal relation of the oculo-orbital nerves from its superior position in the sinus. It is in this situation that it gets communicating fibres from the sympathetic plexus surrounding the internal carotid artery, which passes upwards at the apex of the petrous bone, close to the third nerve in the cavernous sinus. It also receives sensory fibres from the ophthalmic division of the fifth nerve.

Paralysis of the several ocular muscles may be simply classified according to groups of muscles affected as follows: (1) Unilateral partial ophthalmoplegia or paralysis of certain muscles of one eye; (2) unilateral total ophthalmoplegia or paralysis of all the muscles of one eye; (3) bilateral partial ophthalmoplegia; and (4) bilateral total ophthalmoplegia. Ophthalmoplegia may be complete or incomplete according to extent of function interfered with. Unilateral partial ophthalmoplegia is produced by paralysis of the oculomotor nerve, and two distinct forms are found: (1) external ophthalmoplegia—the external muscles of the eyeball are alone affected, excluding the lateral rectus and superior oblique; and (2) internal ophthalmoplegia, in which the internal muscles, the sphincter of the pupil and the ciliary muscle, are paralysed.

---

* A paper read before the Clinical Congress of Surgeons of North America.

External ophthalmoplegia is due to a lesion in the oculo-motor nucleus at its inferior portion, whereas internal ophthalmoplegia is caused by a lesion in the upper or anterior part of the column of origin of the third nerve—the most anterior nuclear group giving origin to the nerve fibres supplying the levator palpebræ superioris. Either an internal or external ophthalmoplegia may follow the other from extension of the lesion. An internal ophthalmoplegia sometimes arises from a lesion inside the orbit due to affection of the short root of the ciliary ganglion, but here is found, in addition, a paralysis of the inferior oblique muscle, and is frequently due to disease in the ethmoidal cells.

Paralysis of all the muscles supplied by the oculomotor nerve, without other muscles being implicated, is caused by a nerve lesion before its entrance to the cavernous sinus, a distance varying from two to three centimetres, and it is usually in this position that disease of the auditory apparatus and temporal bone will attack the nerve by continuity. In the cavernous sinus it is probable that the fifth, fourth, and possibly the sixth nerves will be affected according to whether the pressure is from within the cavernous sinus due to thrombosis or aneurysm of the carotid artery or whether the pressure is on the external sinus wall. Disease of the sphenoidal cell is frequently in causal relationship with this manifestation, since the cavernous sinus and its contents are in close contact with the outer wall of the sphenoidal cavity in varying degrees, as described by Onodi.[1] In the superior orbital fissure the nerve lesion would be accompanied by damage to the other oculo-orbital nerves. In both situations there would be unilateral total ophthalmoplegia. If, however, a lesion affected all the nuclei of the oculo-motor nerve there would be two additional factors—firstly, the crossed fibres passing to the other eye would be affected; and, secondly, the fibres arising from the seventh nucleus to the orbicularis oculi, close to the origin of the fibres of the levator palpebræ, being attacked would cause paralysis of the orbicularis and absence of the usual symptom in complete oculo-motor paralysis, that of the raised eyebrow on the affected side. A further point of importance would be the presence of abducens paresis or paralysis of the opposite side (associated fibres). Slight affection of the lateral rectus and superior oblique is sometimes observed in total paralysis of the third nerve, demonstrated by the field of fixation limitation in the lateral and infero-lateral part (E. Landolt[2]).

Uhthoff has described a recurring ophthalmoplegia in neoplasm of the oculo-motor nerve trunk. Total but transitory ophthalmoplegia, with severe pain, headache, and vomiting, may affect one or other eye, and is nuclear in origin, and spoken of in France as "migraine ophtalmoplégique."

If paralysis of the oculo-motor occurs without affection of abducens and trochlear, and associated with paralysis of the opposite side of the face and body (symptom-complex of Weber), it is suggestive of a lesion on the inner side of the crus cerebri, and is generally due to syphilitic softening, but it may be due to a hæmorrhage or tubercle arising in the temporal bone or base of the skull. The more complete the paralysis of the oculo-motor nerve, the nearer the lesion is to the surface of the crus cerebri after concentration of fibres, and the greater is the lesion. If an irritative lesion exists in the crus cerebri, instead of paralysis there is limitation of the muscles supplied by the third nerve, and on the opposite side of the body contraction or tremors of the limbs, producing what is known as the Benedikt symptom-complex.

Unilateral total ophthalmoplegia can only be caused by a lesion in the orbit, the superior orbital fissure, or in the cavernous sinus. In the region of the orbital fissure it is generally syphilitic. Owing to a thin wall of the sphenoidal sinus and the possibility of dehiscences it may be due to suppuration in that cavity. In cavernous sinus thrombosis there are symptoms of venous congestion; and when there is exophthalmos with pulsation it indicates an arterio-venous aneurysm from rupture of the internal carotid into the cavernous sinus. Other causes of unilateral total ophthalmoplegia are hæmorrhage, exudations, sinus empyema, neoplasms, foreign bodies such as bullets, and thrombosis of orbital veins or veins going to the cavernous sinus from the sphenoidal cavity.

Bilateral partial or bilateral complete ophthalmoplegia are nuclear in origin or due to basal neoplasmata.

As regards the causes of oculo-motor paralysis, I shall limit the description as far as possible to those which arise directly or indirectly from disease of the auditory apparatus or temporal bone, and affecting the second division or basilar portion of the nerve. As to trauma, bullets entering the temporal bone may cause division of or direct pressure on the trunk of the third or other nerves, or indirectly may cause pressure by hæmorrhage or exudation or subsequent inflammation and suppuration in bone or meninges. Inflammation commencing in the middle ear or adnexa may spread by direct cellular continuity to the apex of the petrous portion of the temporal bone. There may be infection and direct extension of pathological processes, streptococcal or staphylococcal in origin, by continuity of tissues and by lymphatics along the vessels, especially the tympanic plexus, and nerves; hence a circumscribed meningitis may be set up and result in nerve pressure or infective toxæmia. Gradenigo was one of the first to establish this. Urbantschitsch first regarded the paralysis as reflex in origin, but this has never been proved except where disease is present in the labyrinth. Thrombosis of veins, more particularly the inferior and superior petrosal sinuses, spreading backwards to the cavernous sinus, may cause pressure on the oculomotor nerve. The former is more likely to affect the abducens, which lies for some distance in contact with them, but thrombosis or periphlebitis may directly attack the third nerve, the specially vulnerable point of which is just before entry into the fold of dura mater split by the trigeminus and the cavernous sinus.

An illuminating case which came under my care is worthy of review because it definitely illustrates the pathological sequence and association of middle-ear disease and oculo-motor paralysis, which is the rarest form of otogenic nerve lesion.

On Nov. 22nd, 1912, I was asked to see a young lady, aged 29 years, when the following history was given. On Nov. 14th she had a sudden attack of vertigo near a hot baking stove. She was inclined to fall, but recovered herself. About 8.30 P.M. she went out of doors, but felt "useless" and returned home. About 9 P.M. she vomited and was purged. Whilst in the bathroom she had an attack of vertigo and fell; got up again, vomited again, and fell once more, striking her head, but did not know where. She thought it was the eye that had been struck when she found she could not open it. There was, however, no mark of bruise or injury. She was unconscious for 16 hours, and vomited during that time. She felt no pain in the head or eye. No vomiting occurred after recovering consciousness.

On Nov. 21st Dr. J. Gray Clegg, an ophthalmic surgeon, was called in, and I am indebted to him for his notes on the examination of the eye. He found complete paralysis of the third nerve on the right side, with ptosis. There was no proptosis and no pain in the eye, but some tenderness on pressure over the upper part of the eyeball. The external rectus and superior oblique were unaffected, the seventh nerve also. The fundus and retinal vessels were normal. He diagnosed pressure on the trunk of the third nerve behind the right orbit. He was told that she had had intermittent slight discharge from the right ear for some years, with a foul odour at times, also slight deafness on that side. There was no history of nasal discharge. The temperature was 99° F. He recommended examination by an aural surgeon.

When asked to see the patient I found her in bed. She was able to answer questions, although she was in a dazed condition. She could hear the voice in an ordinary tone each side, but no specific hearing tests were applied. The nasal cavities presented no evidence of accessory sinus disease. The left ear showed some signs of old catarrhal otitis media. The right meatus was full of brown soft cerumen and cholesteatoma. On removal of this by syringing a perforation ⅛ inch in diameter was seen in the posterior superior quadrant, through which a drop of pus exuded; the remainder of the tympanic membrane was white, thick, and opaque, and the ossicles were not distinguishable. There was no pain in the ear or tenderness over the mastoid process or head. The right eye demonstrated all the classical signs of total paralysis of the oculo-motor nerve. There was ptosis of the right eyelid with very slight protrusion, divergent strabismus, with slight downward rotation, pupil moderately dilated and almost fixed; the right eyebrow was higher than the left. There was no headache or photophobia, but this was present in a slight degree some days later. The fourth, fifth, sixth, and seventh nerves were unaffected. The eyeball could be moved outwards a little further than the rest position, showing the sixth nerve to be free. There was no rotation to the normal side, and upward and downward movements were limited. The right eyebrow was slightly raised above the level of the left one. There was no ecchymosis or œdema of the lids.

On lifting the eyelid and testing the vision it was found that there was crossed diplopia. On placing an object on the axial plane necessitating turning the eyes to the extreme left, the false image was far to the left and inclined towards the affected side. When placed sagitally and below, the false image was below and to the left of the true image; when placed upwards the false image was well above the true image. There was no nystagmus. On testing the pupil reflexes the left one was found to be moderately small and contracted normally to light. The right pupil contracted very slightly, but there was no consensual reflex. Accommodation could not be tested.

From the history and the symptoms present I concluded there was pressure on the oculo-motor nerve, close to the dura mater triangular space before its entry into the cavernous sinus, and near to the apex of the petrous bone. The fourth nerve being free, the pressure was not exerted very far outwards and backwards. There was no intra-orbital pressure, and the superior orbital foramen was free, because the fourth, fifth, and sixth nerves were unaffected. It was because of the cholesteatoma found and the drop of pus on its removal that I advised an exploratory operation through the mastoid antrum. The patient was removed to a nursing home. Menstruation had commenced the day before. After admission she was still drowsy; the temperature was 100° and the pulse 76. Three grains of calomel with castor oil were given. At 6 P.M. the temperature was 101°, pulse 92. She passed a restless night, and next day the temperature was 100°, pulse 84, tension normal, no albuminuria. Nerve reflexes were normal; Kernig's sign was absent. No headache or vomiting; no change in the eye symptoms. She became more drowsy during the day and night.

Operation on Nov. 24th, 10.30 A.M. A post-aural curved incision was made. On chiselling through the dense cortex for 1/16 inch at the antral triangle, the lateral sinus was opened and the vein seen pulsating. This was situated far forwards and close to the sloping wall of the posterior border of the external bony meatus so often observed in the diploetic type of process. A second opening was made above this and the skull cavity was entered, the dura mater being observed to pulsate feebly. The bone between this and the upper and posterior wall of the meatus was extremely dense. At a depth of half an inch from the level of the mastoid cortex the antrum was reached and found to contain pus and fleshy granulations. It was very small, being about 4 millimetres in diameter. On exploration an aperture was discovered in the roof through which pus came after wiping out the cavity. This aperture was about 3 millimetres across. It was enlarged and about half a drachm of pus escaped. A track was found extending inwards for over half an inch, and the bone was removed for that distance. The dura mater did not pulsate and was greyish in appearance. As a little pus could be seen coming from the line of the superior petrosal sinus, a drain of gauze about 1½ inches long was put in. The wound was packed after excising the posterior wall of the cartilaginous meatus.

The temperature dropped to 98·6°, with pulse 92, at 2 P.M., being 99·2° and 88 respectively the same evening. There was no sickness after chloroform, and she slept well the night after operation. Next morning the temperature was 98° and pulse 80. This condition was maintained till 6 P.M. on the 28th, when the temperature reached 100° with pulse 100. She complained of a little headache during the previous night and all that day. She vomited once, at 6.45 P.M. About midnight she had a severe attack of general convulsions, lasting half an hour. There was evacuation of fæces and urine, and a very dark menstrual flow. The temperature was normal, and pulse 80 and very difficult to feel. She was unconscious during the attack, but afterwards spoke rationally on questioning her, and complained of having had a terrible dream. The right eye and cheek were slightly œdematous. The ocular symptoms were the same, and there was no vomiting. The wound was dressed. There was recent blood on the dressing and a little pus in the deep recess of the wound, but otherwise it was healthy. The sinus was pulsating. Bromidia dr. 1 was given and repeated in an hour. She vomited after the second dose, but slept well after a third dose. She slept a good deal day and night after this for several days.

On Dec. 1st the temperature rose to 101·8° and pulse 98. She complained of a little frontal headache. The wound was healthy and there was no pus. The œdema of the eyelid had almost disappeared. There was much constipation, although calomel was given every other day. Quinine and strychnina were also administered. The temperature was normal on Dec. 3rd, and with the exception of a slight rise on the 7th and 8th it remained normal afterwards. She made a slow but uninterrupted recovery.

I saw her again on Jan. 20th, 1913. She was able to get up and about the house, had recovered some of the use of the eye muscles, and the wound was almost healed. The eyelid could be half opened, and the false image was closer to the true image than before operation. I did not see her again till May 23rd, 1913, when she could walk well, but the diplopia confused her out of doors. The ptosis was hardly noticeable and the strabismus slight but discernible. On the normal side the false image was a little to the left, and present still on looking upwards. The fundus was normal. The pupil was a little larger than the left, and reacted fairly well to light and accommodation. Hearing tests: Rinne, right and left, C to C3 negative, C4 positive. Speech, right and left 10 ft. ; whisper, right and left 9 ft. Weber's test lateralised to right. When C tuning fork was placed on the left mastoid it was heard on the right side, the sound appearing to go round the back of the head. Schwabach test C right – 5 sec., left – 3 sec. Watch, right 4 inches, left 7 inches. The right meatus was lined by healthy epithelium. Posteriorly the scar showed slight depression only. I have seen the patient at intervals up to June 29th last, and she has kept perfectly well. There is no ptosis and very slight diplopia on looking upwards only.

In this case the cause was primarily cholesteatoma, which had eroded through the tegmen antri and set up a subdural abscess. The infection worked along the superior petrosal sinus, and so to the trunk of the oculo-motor nerve. It became acute and caused the rapid development of symptoms.

Tröltsch, Ostmann and Hilgermann, cited by Onodi,[1] described similar extension to the petrous apex of purulent otitis media, affecting the oculomotor nerve. Scotti[1] observed destruction of the Gasserian ganglion from necrosis of the apex, after separation and extrusion of a sequestrum through the external auditory meatus. Bircher[1] found oculo-motor paralysis and irritation of the fifth nerve in phlebitis of the lateral, inferior petrosal, and cavernous sinuses, which disappeared after operation. Sikkel[1] records trigeminal neuralgia due to irritation of trigeminus and Gasserian ganglion in otitis media. Jansen[1] and others have described cases of lesions of oculo-motor, together with abducens, trochlearis, and trigeminus, in phlebitis and thrombosis of temporal bone venous sinuses. Sargnon records two cases of complete oculo-motor paralysis with brain symptoms where caries existed in the temporal bone, with disease of the outer wall of the cavernous sinus.

Periodical recurrent paralyses of the third nerve have been reported by Wadsworth, Michel,[3] and others in suppurative otitis media. Michel's case recovered after a free discharge of pus. Wadsworth attributes the phenomenon to inflammatory meningeal changes in the region of the oculo-motor. Eversbusch discusses the possibility of otogenic neuritic change, or of toxic inflammation in these cases, but such a purely toxic effect upon the nerve fibres has not been proved. Toxic neuritis is described by Gerouzi, Baldenweck, Lannois, and Perretière. A recurrent paralysis of the abducens has been observed by Chierici in purulent otitis media, which recovered on free discharge of pus, but reappeared twice afterwards. Abducens paralysis of otogenic origin has been described by several observers, such as Dorello and Baldenweck, some of which remained after operation and cure of the initial lesion (Krepuska). Perkins described 100 cases of abducens paralysis, of which 25 appeared after operation, and in half the cases the Gasserian ganglion was involved. Dorello and Baldenweck point out a direct relationship between the veins of the tympanic cavity and of the inferior petrosal sinus, and of congenital dehiscences in the bone of the anterior wall of the tympanic cavity. Certain ocular reflexes have been observed from otogenic irritation, such as abducens paralysis by way of the vestibular nerve, but no record can be found of similar affection of the oculo-motor nerve.

Paralysis of the oculo-motor nerve has been recorded in temporo-sphenoidal and cerebellar otogenic brain abscess. Lombard[4] believes that when signs of intracranial abscess are present in a suppurative otitis media, if there is oculo-motor paralysis it denotes temporo-sphenoidal abscess, and abducens paralysis indicates cerebellar abscess. Tuberculous or syphilitic disease of the temporal bone may produce oculo-motor paralysis, causing direct pressure on the trunk of the nerve. Otogenic paralysis of the trochlearis has been recorded by Schwartze, De Lapersonne,[5] and others. Jacques twice observed external ophthalmoplegia follow acute otitis media in infants, accompanied by ptosis; one died with all the signs of acute meningitis.

To sum up, it appears that otogenic paralysis of the oculo-motor and other orbital nerves is clearly established, but our difficulty arises when we endeavour to establish the pathological lesion present. When paralysis exists with an ipsolateral otorrhœa, accompanied by headache and vomiting, an exploration of the auditory apparatus should be at once undertaken to determine the extent and limits of the disease, whilst at the same time it should be borne in mind that the examination of the nasal fossæ and accessory cavities may reveal the focus of disease, insomuch as nasal disease infection is far more common than aural infection in the production of paralysis of the oculo-orbital nerves.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF HYDATID CYST OF THE KIDNEY.

By ROBERT E. HALAHAN, M.D. DUB.,
SURGEON TO THE BRITISH HOSPITAL, BUENOS AIRES.

THE patient, a female 23 years of age, had been complaining for some months back of dragging pains in the right loin, sometimes associated with nausea. There was no tenderness on pressure, and the kidney, which was movable, could be felt quite easily. The urine was normal, and no adequate cause could be found for the pains, &c., as the movable kidney seemed hardly likely to produce as much discomfort as the patient complained of. However, I decided to fix it, and on exposing it through a lumbar incision a tumour of about the size of a small orange was found adherent to the convex border. The organ was easily delivered through the wound, and then the nature of the growth was quite obvious.

The cyst was growing on, rather than in, the kidney, extending for only a short distance within the actual kidney substance. The result was that when the tumour was laid open the base presented as a sort of small saucer, about 4 or 5 centimetres in diameter. I decided to cut this base entirely free. Having first passed a short silk ligature round the pedicle of the kidney, ready to tie in case the hæmorrhage became too profuse, a rather flat-shaped wedge of kidney was cut off the cortex in such a way as entirely to remove the base of the cyst, leaving a large open wound. The hæmorrhage was pretty severe, but was controlled by passing catgut sutures through the whole thickness of the kidney so as to embrace the floor of the wound, and tying them as tightly as the kidney substance would allow. In this way the wound was almost completely closed. The skin wound was closed by interrupted sutures and a drainage-tube inserted down to the wound in the kidney. Beyond a urinary fistula which developed on the fifth day, and lasted for 18 days, the convalescence was uneventful, and the patient left completely healed in five weeks.

Buenos Aires.

A CASE OF INTRAUTERINE RUPTURE OF THE UMBILICAL CORD.

By Harold E. Bloxsome, M.R.C.S. Eng., L.R.C.P. Lond.,

SURGEON TO FAIRFORD COTTAGE HOSPITAL; MEDICAL OFFICER AND PUBLIC VACCINATOR, CIRENCESTER AND NORTHLEACH UNIONS.

The patient was a primipara supposed to have been pregnant ten months. When I was sent for she had been in labour for 12 hours. Per vaginam the os was nearly fully dilated, the head was presenting by the vertex, and the pains were severe, the patient describing them as being almost continuous, though there was no distress. The nurse was sure no liquor amnii had come away, but no bag of membranes could be felt. I waited an hour and a half and the os was then fully dilated, though the head had not descended much. Chloroform was given and the forceps applied. As the face swept over the perineum after a moderately hard pull the cord fell out divided in two. There was a large blood clot on each severed end. The child was large and stillborn. There was no sign of pulsation in either part. The placenta subsequently came away in a normal manner. The head had been firmly engaged in the pelvis, and I felt all round the os, so it would have been difficult to have missed a prolapsed cord.

Dr. Herbert Williamson takes the case to be one of a short cord round the child's neck delaying descent and subsequently rupturing. The rarity of such cases is my excuse for bringing it under notice.

Fairford.

NOTE ON A CASE OF CONGENITAL LARYNGEAL STRIDOR.

By J. H. Sheldon, M.B. Lond., &c.

Cases of congenital laryngeal stridor seem to be sufficiently uncommon to warrant the following notes of the first case encountered in nearly 17 years of general practice.

The patient, seen in February, 1914, was a well-nourished male Madrassee infant, 5 months of age, born prematurely in the eighth month of the mother's first pregnancy and hand-fed from birth. The infant's medical history was good and he presented no signs of syphilis or rickets. One tooth was almost through. He was bright and intelligent. The family history indicated nothing except the occurrence of asthma in the children of an aunt of the patient's father. The chief features of the case were: (1) stridor present from birth; (2) transverse furrowing of the lower chest wall; (3) certain auscultatory signs; (4) absence of cyanosis; (5) absence of laryngeal excursion; (6) a heart-rate uninfluenced by respiratory movements; and (7) the excellent health of the child. The stridor accompanied each inspiration, and, with the exceptions to be given, was always present, both sleeping and waking. It disappeared for short periods (half an hour) during sleep and for shorter periods while the child lay awake quiet and with his attention fixed, and while taking the bottle. The sound produced was for the most part a hoarse and low-pitched crowing of varying loudness, but generally heard at a distance of some yards. When the child was excited the stridor became loud and shrill (high pitched). I was informed that the noise was not noticeable when the child cried. During a quiet period the shape of the chest was almost normal, though the sternum was slightly prominent and indications of a transverse lateral sulcus were seen. There was no parasternal grooving. During periods of stridor each inspiration was accompanied by great recession of the lower ribs and costal margin opposite the ensiform cartilage, and the formation of a deep transverse sulcus extending out from the costal margin almost to the anterior axillary line. The alæ nasi dilated with each inspiration. The inspiratory murmur during stridor was interrupted and subdivided sometimes into two, sometimes three separate and distinct sounds. Expiration was unaltered. There were no adventitious sounds.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases.—Cysts in the Anterior Chamber.

A meeting of this section was held on Nov. 4th, Mr. **Priestley Smith**, the President, being in the chair.

Dr. A. **Hugh Thompson** showed a young girl who had Dilated Pupil of Argyll Robertson type, with well-marked contraction on closure of lids. The condition was not congenital in her, because two years ago her pupils were normal and she had only slight myopia. The knee-jerks were normal. He also exhibited a case of One-sided Internal Ophthalmoplegia. The man was invalided two years ago on account of supposed aneurysm. No aneurysm had been found, though he was carefully examined by Sir John Broadbent.—Mr. W. C. **Rockcliffe** spoke of two cases in his experience with mydriasis and iridocycloplegia. In one there was a strong family history of retinitis pigmentosa, but in the patient there was no retinal or pigmentary change. One patient's end was in an asylum as a general paralytic.

Mr. N. **Bishop Harman** showed a case of Congenital Entropion. The lashes in the lower lid were permanently erect and the child was born with the condition. The meibomian glands seemed deficient. The mother was normal, but the grandmother was said to have had a double row of lashes. He proposed to split the lid, so as to separate the lashes from the glands, and graft between the two a strip of mucous membrane. If that succeeded he expected the lashes would be prevented from reaching the cornea again.—Mr. M. S. **Mayou** referred to three similar cases which he had had. He operated upon them by taking out a narrow band of skin on the outer side of the lid. There had been no recurrence, though one was operated upon five years ago.

Mr. **Bishop Harman** read notes of a case of High Myopia in an infant.

Mr. W. H. H. **Jessop** showed a case of Tumour of the Lower Lid which he regarded as a lymphangioma. A former term applied to it was elephantiasis nostras. Skiagrams showed nothing abnormal about the bones, and skilled nasal investigation was negative.—Lieutenant-Colonel R. H. **Elliot**, I.M.S., mentioned a similar case which he saw in India, and which was found to be sporotrichosis ochonelia.—Mr. **Leslie J. Paton** said he had seen a similar case following the extensive scarring of lupus, and there was complete blockage of the lymphatic ducts draining the eyelid. He sent the case to a colleague with the request that he would establish a permanent drain into the lymphatics of the lip.—Mr. **HARMAN** reminded members of a case shown at the Laryngological Section in which draining was done into the neck, and answered fairly well.

Mr. A. W. **ORMOND** exhibited a doubtful case for diagnosis, which was generally regarded as inflammatory.

Mr. H. L. **EASON** exhibited an interesting example of Confluent Tubercle of Iris. Tuberculin had not improved it. As perforation was occurring in the ciliary region, the only course was removal of the eye. He had had a case in which perforation occurred in three weeks; in this case it commenced in the fifth week of the history.

Mr. A. H. P. **DAWNAY** showed a patient suffering from Intra-ocular Metastatic Carcinoma.

Mr. W. T. **HOLMES SPICER** read a communication entitled "Cysts in the Anterior Chamber arising from the Pars Ciliaris Retinæ," and illustrated it by a number of slides. The case had been under observation seven years; it began with a white spot at the edge of the pupil at 3 months of age. At 16 months, when first seen, there were three opaque finger-shaped masses coming into the anterior chamber from behind the iris. Four years later these had disappeared, and a cyst about 4 mm. in diameter was seen floating freely in the anterior chamber. Other cysts appeared later, and finally there were seven, floating like toy balloons in the anterior chamber. In the meantime the eye had become glaucomatous, a ciliary staphyloma had formed, and the eye was removed. The pathological examination was made by Mr. Greeves. It was found that the cysts were formed of embryonic retinal tissue containing vitreous. They had their origin in the pars ciliaris retinæ, starting from cellular membranes, which grew over the iris and also into the vitreous; the cysts grew on the surface of these membranes. There was in many places in the walls of the cysts a resemblance to glioma tissue. The case further proved the non-mesoblastic origin of the vitreous.—Mr. **TREACHER COLLINS**, discussing the case, said it bore out the view of embryologists that the vitreous humour was derived from neural epiblast; it further showed it was derived from only one portion of it.—Mr. **MAYOU** referred to a case of his own in which there was a pigmented tumour in a microphthalmic eye, consisting of epithelial cells. It only occupied an eighth of the segment of the ciliary body.—Mr. W. **LANG** spoke of a case he saw with Professor Fuchs in which there was a semi-translucent brownish cyst in the anterior chamber. Since then he had had a similar case of his own, but an attempt to deal operatively with it was not a success.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Coxalgic Pelvis: its Lateral Tilting.

A **MEETING** of this society was held in Liverpool on Oct. 16th, Dr. J. H. **WILLETT**, the President, being in the chair.

Dr. W. K. **WALLS** (Manchester) exhibited a specimen of Double Hydrosalpinx and Tubo-ovarian Cysts removed with the body of the Uterus from a young woman, married some months, whose appendix had been removed a few years previously.

Dr. W. E. **FOTHERGILL** (Manchester) described a case of Double Uterus with Right Pyocolpos. This case presented great difficulties in diagnosis. The patient was a virgin, aged 22 years, with normal menstruation, who complained of pelvic pain of some days' duration and had a raised pulse and temperature. On examination two masses could be felt which, on account of the symptoms, were taken to be the uterus and a matted appendage. The abdomen was opened and the masses found to be the two halves of a double uterus, with no sign of inflammation, below which, on the right side, a fluctuant swelling could be felt. This swelling was opened from the vagina and proved to be the occluded right half of the vagina filled with pus.

Dr. J. E. **GEMMELL** (Liverpool) exhibited a specimen of Adenocarcinoma of the Uterus, removed from a patient, aged 52 years, who complained of pain and a slight vaginal discharge.

Dr. H. **BRIGGS** (Liverpool) showed: (1) A specimen of a Soft Resilient Interstitial Uterine Fibroid from a woman, aged 30 years, on which there was great difficulty in making a diagnosis between fibroid and pregnancy; (2) a Stony Hard Fibroid which was difficult to diagnose from an ovarian fibroma; and (3) a Uterus from a case of post-climacteric hæmorrhage.

Dr. W. **FLETCHER SHAW** (Manchester) described a case of Septic Miscarriage followed by Intestinal Obstruction. The obstruction occurred a fortnight after the miscarriage, which had been followed by sepsis, the symptoms of which had abated. An abdominal section revealed a loop of small intestine adherent to a mass of glands in the region of the sacral promontory. The loop was freed and the patient did very well for two days, when acute peritonitis supervened, for which the abdomen was again opened and drained. The patient made a good recovery. In all probability the glands were enlarged from the septic uterus.

Dr. **BRIGGS** read a note on the Coxalgic Pelvis: its Lateral Tilting. He described a specimen from the pathological museum which was mounted by the surgeons with the diseased side lowest. He discussed the specimen from the obstetricians' point of view, which was that the specimen should have been mounted with the diseased side highest.

ÆSCULAPIAN SOCIETY. — A meeting of this society was held on Oct. 6th, Dr. David Ross being in the chair.—Dr. Philip Hamill read a paper on Obesity. He said obesity may be defined as a considerable excess of body weight over the accepted standards for normal individuals of the same height and age. The chief disadvantage of obesity lies in the increased work and strain on the heart during bodily exertion. Respiration and cardiac efficiency are hampered by a corpulent abdomen, and the obese are frequently short-winded, emphysematous, and bronchitic. They possess a lower resistance to acute infections and are unfavourable subjects for operations. Gout and vascular affections are common in obesity, and chronic interstitial nephritis frequently develops. In young subjects and adolescents obesity is not uncommonly associated with delayed puberty; the majority of these subjects became normal during the third decade. A certain number of cases of obesity appear to be associated with deficient pituitary or thyroid secretion, as in Fröhlich's syndrome, adiposis dolorosa, and myxœdema. In obesity the increase of fat is the result of an intake of food in excess of the energy requirements of the body. Very slight habitual excess will in time produce a considerable increase in fat; thus a daily excess of ½ oz. of fat, or of the nutriment represented by ½ pint of ale will account for an increase of 1 st. in weight in the course of a year. Obesity commonly manifests itself about the age of 40, at which time most persons diminish the amount of exercise taken in walking, games, &c.; at the same time, prosperity is commonly associated with a more liberal diet. Temperament is an important factor; those of a phlegmatic, restful habit put on flesh, whilst others of active disposition who constantly make small movements remain thin, for these slight differences in activity account for a considerable expenditure of energy in the course of a day. It is probable that temperament is the most important factor in heredity and racial tendencies to obesity. Steps should be taken to reduce obesity when it is excessive or when it interferes with the functions of any organ. Reduction is particularly indicated in gouty individuals, but is contraindicated in the aged and in the presence of diabetes, however mild, tuberculosis, and manifest renal disease. It should be noted that many obese individuals develop chronic interstitial nephritis, consequently in presence of raised blood pressure reduction should be gradual to avoid precipitating the onset of the disease. Rapid reduction of fat is liable to produce muscular and cardiac weakness, and should not be undertaken unless the patient is under close observation in an institution. Except in special circumstances it is always desirable to proceed slowly and to vary the patient's conditions of life as little as possible consistent with attaining the desired result. He is thus gradually educated to a rule of life, and is then less likely to relapse. The weakness and exhaustion which commonly follow rapid reduction result in diminished activity and overfeeding, with the result that the lost weight is speedily regained. A loss of one or two pounds monthly for the first six months is ample in most cases, and for the rest of the first year half this rate of reduction suffices. In general the careful avoidance of fat, restriction of alcohol, and very slight restriction of carbohydrates will bring about the desired result. Great restriction of carbohydrates is not desirable. Walking on a gentle incline is a valuable form of exercise which can be accurately measured and which strengthens the heart. Massage is useful in anæmic patients for improving muscular tone and enabling them to take exercise without exhaustion. Special attention should be devoted to improving the tone of the abdominal muscles in order to guard against unpleasant sensations associated with the diminution of the omental fat. Cold baths are useful where applicable; thyroid is not advisable in other than myxœdematous patients; and iron and strychnine are particularly valuable in anæmic obesity.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Oct. 22nd, Mr. J. Jackson Clarke, the President, being in the chair, when a number of clinical cases were shown.—The President showed a series of four cases of Gunshot Fractures incurred in the war. One of these was a comminuted fracture of the humerus caused by a rifle bullet; the remainder were due to shrapnel.—Dr. S. Melville spoke of the difficulties met with in the localisation of bullets by X rays.—The cases were discussed by Mr. V. Z. Cope, who recounted an example of severe shrapnel wound in the forearm. Troublesome hæmorrhage had occurred some time after the injury. The bleeding points were widely distributed all over the wound. Apparently both the radial and ulnar arteries had been severed and a free anastomosis had resulted.—Dr. Leonard G. Guthrie showed a case of Congenital Syphilis of the Nervous System in a girl. The knee-jerks were absent, but there was bilateral extensor plantar response. The gait was typical neither of cerebellar nor spinal ataxy. She walked in an awkward shuffling manner, swaying the trunk from side to side, the feet everted, with a tendency to drag them. The pupils reacted neither to light nor to accommodation. There were pegged teeth and old disseminated choroiditis. The Wassermann reaction of the blood was positive. Her mental capacity was good.—Sir John Broadbent showed a case of Pulmonary Stenosis, and also one of Aortic Regurgitation and Stenosis with Mitral Stenosis.—Dr. W. H. Willcox showed cases of Temporo-sphenoidal Tumour; Rat-bite Fever in a boy, in which the symptoms were recurrent fever and erythema; Neoplasm of the Stomach, in which a large stomach tumour had arisen without previous gastric symptoms, and which was thought to be a sarcoma; and Pituitary Tumour in a man who had the usual evidences of acromegaly. —Dr. Frederick Langmead showed a case of Congenital Family Cholæmia. It was that of a man, aged 45, whose two daughters, aged 4 and 6 respectively, suffered from the same complaint. The usual features were present except increased fragility of the red blood cells. The question of splenectomy was raised.—Dr. G. de Bec Turtle showed a case of ? Patent Ductus Arteriosus in an adult. A systolic murmur was audible with greatest intensity in the pulmonary area, but not in the back. Signs of heart failure were present.

McQUITTY MEMORIAL PRIZE.—This prize for 1914 has been awarded to Mr. A Fullerton, M.B. The prize, which is open to students in their final year at the Royal Victoria Hospital, Belfast—the subjects being medicine, surgery, gynæcology, pathology, and ophthalmology—was founded as a memorial of the late Dr. W. B. McQuitty.

THE LATE SIR KAI HO KAI, M.B.—At a meeting of the University Lodge of Hong-Kong (No. 3666) the Worshipful Master, Dr. Francis W. Clark, made eloquent reference to the death of Sir Kai Ho Kai, C.M.G., M.B., C.M. Aberd., barrister-at-law. "One of the small band of pioneers who realised, even 30 years ago, that the future of China's greatness lay in the hands of those of his countrymen who were prepared to share the knowledge and the science of the West." Sir Kai Ho Kai was a founder of the Hong-Kong College of Medicine and one of the prime movers in the establishment of the University.

Reviews and Notices of Books.

Anoci-Association.

By GEORGE W. CRILE, M.D., Professor of Surgery, Western Reserve University, Visiting Surgeon to the Lakeside Hospital, Cleveland; and WILLIAM E. LOWER, M.D., Associate Professor of Genito-Urinary Surgery, Western Reserve University, Cleveland. Edited by AMY F. ROWLAND. Original illustrations. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 200. Price 13*s.* net.

AT a first glance the title of this monograph may to many seem somewhat strange. To those, however, who are familiar with the modern nomenclature of the receptor mechanisms of the body it presents no difficulties. All of life is filled with *noci-associations*—injurious if you will—as a result of which the stored energies of the body are constantly drained. The *noci-ceptors* are richly implanted in the skin. The object of the authors is to consider the pathology of shock in its varied aspects—traumatic, emotional, toxin and protein shock, drug shock, and the practical application of the kinetic theory of shock in the development of the *shockless operation* through anoci-association.

All successful surgery must finally be based on physiological principles. For long it was supposed that if the patient during an operation was thoroughly anæsthetised and infection avoided, the operation itself—apart from the actual traumatic intentional lesions—had but little effect on the economy. An account is given of the kinetic theory of shock and the principle of anoci-association, and the application of the kinetic theory to the technique of surgical operations is described.

Crile's physiological and surgical experiments led him to conclude that shock is "the result of exhaustion," and that one of the most vital phenomena accompanying shock is a low blood pressure and the impairment of the vaso-motor mechanism. Shock is most conspicuously diminished by morphine administered hypodermically and by local and regional anæsthesia. Careful handling, sharp dissection, and minimum trauma are also very effective in preventing shock. The preventive technique of shock—i.e., all the measures and methods available—is grouped under the term anoci-association. The ideal treatment for surgical shock is the direct transfusion of blood, but of course for the human subject this is not always available. Further researches showed that the brain cells, the suprarenals, and the liver give an excellent index to the degree of shock, whether from trauma, drugs, toxins, or anaphylactic and foreign proteins, and that these stimuli do not cause histological changes in any other organs. Very instructive and striking histological coloured illustrations are given to show the changes in the cells of the organs mentioned. Each shock-producing agency at first causes in the brain cells a hyperchromatic stage followed by a hypochromatic stage. Heavy morphine doses produce no especial changes in the organs mentioned. These changes do not appear to be due primarily to products of pathological metabolism or to altered gases in the blood, though these are secondary factors. Nor are the changes in the brain cells due to the inhalation anæsthetic *per se*, yet their extent is to a considerable degree determined by the anæsthetic which is used in a surgical operation. All these changes are less marked under nitrous-oxide-oxygen than under ether; the inference from the teaching is that the former should be the inhalation anæsthetic of choice.

The degree of shock is dependent upon the part of the body injured, and varies with the type of trauma inflicted. The severely depressing effects of stimulation of the distance ceptors, and the emotions, especially fear, are fully expounded. As to the treatment of shock, two important points must be borne in mind: (1) the prevention of further shock by the amelioration or elimination of conditions which produce it; and (2) the support of the circulation. The indications are:—Check hæmorrhage, blunt the susceptibilities, and quiet apprehension. Morphine for this purpose is "the surgeon's sheet-anchor." To mitigate the pre-operative dread and to facilitate the induction of anæsthesia, a solacing dose of morphine (1/6th gr.) and scopolamine (1/150th gr.) is given before the operation. In the choice of an anæsthetic, as the patient is the first consideration, every division of a sensitive tissue is preceded by the injection of novocain in 1 in 400 solution. To minimise post-operative discomfort, especially in abdominal operations, quinine and urea hydrochloride in a 1/6 to 1/2 per cent. solution is injected *at a distance* from the wound. There should be gentle manipulation and sharp dissection, and tissue trauma should be as slight as possible. Local anæsthesia is of the greatest importance. Most illuminating and thoroughly practical descriptions are given of the requisite anoci-associations in abdominal operations, operations on the gall-bladder, stomach, intestines, bladder (in this case the mucosa is anæsthetised by an injection of 5 per cent. solution of alypin), uterus, perineum, rectum, and kidney. Benign and malignant tumours are considered and the special conditions arising in Graves's disease and cerebral surgery. One chapter is devoted to the technique of administering nitrous-oxide-oxygen.

This suggestive monograph, which marks a most important advance in surgical technique, should be in the hands of every surgeon, and its principles should be tested in their application to different surgical operations. We congratulate Professor Crile and his coadjutors on their work.

A Text-book of the Practice of Medicine.

By JAMES M. ANDERS, M.D., Ph.D. Eleventh edition, illustrated. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 1335. Price 24*s*. net.

The Practice of Medicine.

By JAMES TYSON, M.D., LL.D., and M. HOWARD FUSSELL, M.D. Sixth edition. With 6 plates and 179 illustrations. Philadelphia: P. Blakiston's Son and Co. 1914. Pp. 1211.

Modern Surgery, General and Operative.

By JOHN CHALMERS DACOSTA, M.D., LL.D., Samuel D. Gross Professor of Surgery, Jefferson Medical College, Philadelphia. Seventh edition, revised, enlarged, and reset. With 1085 illustrations, some of them in colours. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 1515. Price 25*s*. net.

THE ideal text-book of medicine has yet to be written. There are many books which treat of diseases in a systemic manner, and partition off, under definite headings, the various diseased states that are met with; but although these may be of use to the student who has to acquire a comprehensive survey of the whole field of medical practice, they fail to be of use to the practitioner who, at an early date, has forced upon him the fact that diseased states rarely conform to type.

We are inclined to think that modern text-books of medicine approach more and more to dictionaries rather than text-books, dictionaries which must perforce throw the greatest strain on the memory of the student, whereas we are almost sure that the thinking student and the observant practitioner would be better served by text-books in which the subjects were treated on broader lines, and, in fact, in which general principles were brought into play, so that they would have constantly put before them disease as the disturbance of physiological and anatomical states.

The two books on medicine before us are of the old type in which the diseases are systematised and in which no attempt at continuity of ideas is made. Both have run through many editions, so that little need be said in the way of review. Both have been favourably received by us on previous occasions, and in so far as they go we can only say again that they fulfil the object of the writers. They have been brought up to date by the addition of much recent work on medicine in all parts of the world. Professor Anders's book is perhaps a little fuller than the joint work of Dr. Tyson and Dr. Howard Fussell. He has added considerably to his useful tables of differential diagnosis, and gives many prescriptions which he has personally tried and found satisfactory. Both books will prove of great value and keep up their reputation for being standard text-books on medicine. And their limitations are those of all text-books that are written by individuals who cannot be personally responsible for the views on all the aspects of so illimitable a subject. There must be present in such works opinions on many subjects which are handed down from text-book to text-book; no isolated author feels brave enough to break the entail or to open up new ground. For instance, the erroneous idea of the etiological relationship between alcohol and hepatic cirrhosis should not appear without criticism. The important part played by B. coli and its allies in the production of disease and the interesting question of streptotrichoses deserve fuller treatment than they obtain. But it is easier to criticise than actually to suggest how a perfect medical text-book should be written, and we merely express the general feeling that text-books of medicine have their necessary limitations, which are sometimes unfortunate. But concerning these two special works under review, we can only repeat that they are exceedingly good examples of their type, and we reiterate the favourable opinions we expressed in our reviews of the earlier editions.

There is little fresh to say about the seventh edition of such a work as the text-book of modern surgery by Dr. DaCosta. The preceding editions were good and this issue is thoroughly representative of present-day surgery. But the more concrete nature of surgical teaching seems to remove the surgical text-book from some of the drawbacks which characterise the medical text-book.

In his preface the author explains the great difficulty of a writer of a text-book: he has to decide whether "an alleged discovery is a fragment of eternal truth or a nebulous emanation of chaos," and on the judgment of the author in this respect depends in great degree the real character of the book. The author appears to us to view surgery with an open mind, so that he has been able to decide wisely between the rival claims of recent additions to the science, and the whole work may be taken to represent the present state of surgery; yet he has found it possible to keep the book within a reasonable size.

There is another point which deserves mention; he has endeavoured to give the authority for every important statement, and when possible to use the author's words, believing that an author's description of his own work must be better than any description that could be written for him. These numerous references must prove very useful to the reader who wishes to investigate any subject more fully, and we agree that as a rule an author can describe his own work best, though the rule is not without exceptions, for a surgeon may have the power of devising a method and yet not possess the ability to describe the method so clearly that others may grasp it readily.

The work is probably the best general text-book of surgery emanating from the United States of America.

Practical Therapeutics, Including Materia Medica and Prescription Writing.

By DANIEL M. HOYT, M.D., Assistant Physician to the Philadelphia General Hospital. Second edition. London: H. Kimpton. 1914. Pp. 426. Price 21*s.* net.

THIS book is mostly headlines and spaces, with the baldest information under the headings. Under each drug is given a section on physiological action, one on the different preparations of that drug, and another on its therapeutic application; but no one would gather from this volume that opium was a more important drug than, say, camphor, or that the state of the pupils in opium poisoning was of any more importance than in poisoning by other drugs.

The volume is full of minor mistakes. It is true that in the United States a fluid pint contains only 16 ounces, but in a book intended apparently for use in this country the difference between the United States and the British measures should be made clear. The author makes much of the rules for prescribing, but his prescriptions show none of the meticulous care which specimen prescriptions in an elementary text-book should undoubtedly display. In teaching a student to prescribe he should be told to specify whether the ingredients of a prescription are to constitute a draught, a lotion, or a gargle, &c., and to send out a box of suppositories labelled "One at night," as the author's instruction runs, might with ignorant patients lead them to appreciate the flavour of oil of theobroma.

In a book of this elementary character the photographs of tracings of physiological experiments are quite out of place, excellent as they are in themselves, while the picture of a cardiographic apparatus on p. 32 shows nothing which would be comprehensible to one who had never seen such an apparatus. The best chapter is that on proprietary medicines and meat juices. Here the author writes with courage and knowledge.

1. *Bakteriologische Untersuchungen der Genitalsecrete der nichtschwangeren und nichtpuerperalen Frauen, &c.*

By Dr. MAUNU AF HEURLIN. Pp. 226. Price 12 marks.

2. *Bakteriologische Untersuchungen des Keimgehaltes im Genitalcanale der fiebernden Wöchnerinnen, &c.*

By Dr. MAUNU AF HEURLIN. Berlin: S. Karger. 1914. Pp. 616. Price 12 marks.

THESE two monographs by Dr. Heurlin embody the results of prolonged and painstaking researches into the bacterial flora of the female genital passages and the reaction of the vaginal secretion. The conclusions arrived at, briefly summarised, are that the vaginal secretion in young children is alkaline in reaction to litmus, but becomes acid about the time of puberty, and remains so in healthy subjects till the involution of the genital apparatus in advancing age, when it once more is alkaline. A temporary change to alkalinity may occur during the puerperium and last till the cessation of the lochia, and in disease, especially gonorrhœa, an alkaline condition is often present. On the other hand, the secretion of the cervix uteri is normally alkaline throughout life. The bacteria present in the vagina are originally derived from the intestine, and the type of flora encountered varies with the condition of the vaginal secretion. In young children Gram-positive cocci and facultative anaerobic streptococci predominate. With the acid secretion of healthy adult life the organisms found in greatest numbers are the different kinds of vaginal bacilli, of which the author distinguishes six varieties. He classifies the conditions of the vagina into four degrees of cleanliness according to the bacteria present, the least contaminated or first class showing a prevalence of vaginal bacilli in practically pure culture, the second class a mixture of these bacilli with comma variabile, the third the coexistence of the latter organism with streptococcus anaerobius carduus, and the fourth, or most contaminated, class presenting only this streptococcus and other anaerobic cocci, with few or no bacilli or commas. This last class comprises chiefly old women and young children in whom the alkaline secretion facilitates the growth of such organisms. The vaginal secretion of a healthy woman contains few leucocytes, but these cells increase in cases of abnormal uterine positions. Some of the anaerobic organisms found in the healthy vagina are identical with those found in febrile patients after parturition and are responsible for the pyrexial disturbance, gaining an opportunity for rapid multiplication at this time. Streptococcus pyogenes is not often, in the author's experience, responsible for this rise of temperature, nor has retention of membrane or rupture of the perineum any very constant connexion with the occurrence of a febrile state after labour.

A Manual of Dental Anatomy (Human and Comparative).

By CHARLES S. TOMES, LL.D., F.R.S., F.R.C.S. Eng. Seventh edition. With 299 illustrations. Edited by H. W. MARETT TIMS, M.A. Cantab., M.D. Edin., and A. HOPEWELL-SMITH, M.R.C.S. Eng., L.R.C.P. Lond., L.D.S. Eng. London: J. and A. Churchill. 1914. Pp. 616. Price 15*s.*

THE seventh edition of this well-known text-book has been brought out under the joint editorship of Dr. Marett Tims and Mr. Hopewell-Smith, and we may at the outset say that the editors have carried out their task in a most admirable manner. Tomes's "Dental Anatomy" is not only the recognised text-book for dental students, but it is also freely used by the student of general zoology. The requirements of these two classes of students are somewhat divergent, and with a view of meeting these requirements the editors have divided the book into two parts. The facts dealt with in Part I. are those more immediately demanding the attention of the dental student, while those in Part II. are of great importance to the student of comparative anatomy.

The account given of the dental tissues is admirable, and the various views on debatable points are placed before the readers in a clear and well-balanced way. Reference is made to the analysis of enamel carried out by Mr. Lovatt Evans, which shows that dried human enamel contains organic matter probably to the amount of 1 to 2 per cent. The chapter devoted to the naked-eye anatomy of the teeth still leaves much to be desired. It may be hoped that in future editions a fuller description and one better illustrated will be given.

Professor Fawcett's recent work on the development of the maxilla and mandible in man is clearly described, and several illustrations have been added to assist the description given in the text. In the part of the book devoted to comparative odontology the order in which the different groups are discussed has been brought into line with modern ideas. A welcome account is given of the teeth of prehistoric man, and as bearing upon this question we think it would be useful to extend the descriptions of the teeth of anthropoid apes and the monkeys. To each chapter a list of references has been added.

Technik der speziellen klinischen Untersuchungsmethoden.

By 12 writers. Edited by Professor Dr. T. BRUGSCH and Professor Dr. A. SCHITTENHELM. Part II. Berlin and Vienna: Urban und Schwarzenberg. 1914. Pp. xvi. + 523–1078. With 115 figures in the text, one coloured plate, and one table. Price, paper, 36 marks; bound 40 marks.

THE first part of this large text-book was reviewed in THE LANCET of May 23rd last. The second part is subdivided into six sections. In the first of these are considered the various methods of investigating the metabolism of human beings; in the second section a large number of special chemical methods—quantitative, qualitative, and biochemical—are described. The third section is devoted to various experimental methods used in the investigation of the many ferments or enzymes met with in the body. Next comes a brief account of the functional examination of the vegetative nervous system, and after that an exposition of the chief physico-chemical methods that are of service in medicine; an admirable account of colloid chemistry is given here, erring, perhaps, on the side of excessive brevity. Ten pages at the end of the text are devoted to bodily measurements and their normal figures, and the book ends with a satisfactory index. The editors are to be congratulated on the success with which they have laboured to produce a technical laboratory manual of reasonable size. It contains directions for the performance of tests and analyses in the greatest variety; the experimental methods are described briefly, and many of the directions and manipulations could only be understood and carried out by experts in the use of physical or chemical apparatus, but references to the literature are given and should suffice to fill in any lacunæ. One may sometimes be in doubt as to the value, in any clinical sense, of the results furnished by the tests or analyses described. Thus the importance of estimating the quantity of peroxidase in animal extracts or substances, or of measuring the viscosity of the blood, or of titrating the amount of trimethylamine in the urine, may not be immediately apparent to the physician, possibly because he lacks experience. But for those who have to carry out these and many other examinations of normal or pathological excretions and tissues, Brugsch and Schittenhelm's volumes are indispensable.

LIBRARY TABLE.

Studies from the Rockefeller Institute for Medical Research. Reprints. Volume XVIII. New York: The Rockefeller Institute. 1914. Pp. 596.—The contents of this volume consist of 27 papers on pathology and bacteriology, 4 papers on physiology and pharmacology, 5 papers on chemistry, 4 papers on experimental surgery, 9 papers on experimental biology, and 11 papers from the Hospital of the Rockefeller Institute. The first paper, the Huxley lecture, by Simon Flexner, on Some Problems in Infection and its Control, was published in THE LANCET of Nov. 9th, 1912. The greater portion of the remaining papers are from the *Journal of Experimental Medicine*, though several American and German medical, zoological, and other scientific journals are represented. We mention only a few of the subjects and select those bearing more especially on the practice of medicine. Peyton Rous, James B. Murphy, and W. H. Tytler, and Rous and Murphy later, treat of a filterable agent as a cause of osteochondrosarcoma; F. G. Novy, W. A. Perkins, and R. Chambers, of immunisation by Trypanosoma lewisi; Mary E. Morse, of complement fixation and the diphtheria group of organisms. The spleen and hæmolytic jaundice forms the subject of papers by R. M. Pearce, J. H. Austin, and J. H. Musser, jun., by H. T. Karsner and R. M. Pearce, and by R. M. Pearce and J. H. Austin. H. Noguchi has cultivated a new species, Treponema calligyrum, from human condylomata, and has studied spirochæta pallida in the central nervous system in progressive paralysis and tabes dorsalis. He also writes (with J. W. Moore) on Treponema pallidum in the brain in general paralysis. Poliomyelitis is the subject of studies by C. W. Howard and P. F. Clark (insect transmission), S. Flexner, P. F. Clark and F. R. Fraser (passive human carriage), and S. Flexner and H. Noguchi (cultivation of virus). S. Flexner gives the results in 1300 cases of serum treatment in epidemic meningitis. E. E. Butterfield and F. W. Peabody consider the action of the pneumococcus on blood, and Martha Wollstein and S. J. Meltzer the production of pneumonic lesions by intrabronchial insufflation of non-virulent pneumococci and the reaction of the lungs to intrabronchial insufflation of killed virulent pneumococci and of plain sterile bouillon. S. J. Meltzer gives simple devices for emergency artificial respiration. Alexis Carrel studies visceral organisms. F. H. McCrudden and H. L. Fales study infantilism with special reference to nitrogenous compounds and excessive calcium excretion in the fæces, intestinal absorption, and the cause of failure to develop (four papers). Francis W. Peabody studies inorganic metabolism in pneumonia. H. F. Swift reports absorption of arsenic following intramuscular injections of salvarsan and neosalvarsan. The various papers are reprinted in series and consecutively numbered, and there is a good index.

Photography in Colours: A Text-book for Amateurs and Students of Physics, with a Chapter on Kinematography in the Colours of Nature. By GEORGE LINDSAY JOHNSON, M.A., M.D., B.S. Cantab., F.R.C.S. Eng. With 13 full-page plates (5 in colour) and numerous illustrations in the text. London: George Routledge and Sons, Limited; New York: E. P. Dutton and Co. 1914. Pp. 243. Price 3*s.* 6*d.* net.—The first edition of this book was reviewed in THE LANCET of Feb. 18th, 1911. The second edition has been enlarged from 143 to 243 pages, largely by amplification of the descriptions of colour processes other than single-plate colour photography. A chapter has been added on the "uto-colour" process of printing in colour direct from colour photographs. The chapter on the nature of light, colour, and shadows deals, perforce inadequately in 28 pages, with such abstruse subjects as the wave and electro-magnetic theories of light, shadows, the colour of the sky, and so on. The book will be useful to those who wish to obtain an idea of the principles of colour photography and as an introduction to the practical application of the art.

Psychiatrische Vorträge für Aerzte, Erzieher, und Eltern. Dritte Serie. Von Professor Dr. G. ANTON, Direktor der Klinik für Nerven- und Geisteskranke in Halle. Berlin: S. Karger. 1914. Pp. 91. Price 2.40 marks.—Professor Anton continues his series of essays on psychiatrical subjects, intended for parents and teachers as well as for physicians. On this occasion we feel that the majority of the essays are concerned with such technical matters and couched in such technical language as surely to fail to appeal much to the former divisions of his audience. The paper on return of function in disease of the brain and cord is interesting and instructive. It deals with the question of the vicarious functioning of one part of the brain for another, the whole matter of compensation, and the relation between development and function; it will repay perusal in the original. Another essay is entitled "Gehirnbau und Seelenkunde," and is concerned with the interrelation of cerebral structure and psychical function. The facts of cerebral pathology are utilised to exemplify the changes in the psyche consecutive to lesions in various of the lobes of the cerebrum. An article on the inner associations between thinking and speaking is also worth notice. Other papers are entitled "Gefährliche Menschentypen" and "Geistige Artung und Rechte der Frauen." In the latter Professor Anton states that physically and psychically woman is of a different type from man; her organism has different limits and obeys different laws, but he declares that the champions of the women's movement have overridden the limits imposed by nature.

A Short Handbook of Cosmetics, by Dr. MAX JOSEPH, of Berlin (London: Heinemann. 1914. Pp. 97. Price 2*s.* 6*d.* net), has reached its second English edition. This little volume deals with those conditions which as a rule come under the notice of the dermatologist rather than of the general practitioner. It contains answers to questions frequently put by the public, and if the doctor considers these subjects beneath the dignity of science, the patient will seek the advice of less competent and unqualified practitioners. In the right hands Dr. Joseph's book should prove exceedingly useful.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, R. HUTCHISON, A. E. GARROD, H. D. ROLLESTON, and W. HALE WHITE. Vol. VIII., No. 29. October, 1914. Oxford: at the Clarendon Press. London, Edinburgh, New York, Toronto, and Melbourne: Humphrey Milford. Subscription 25*s.* per annum; single numbers 8*s.* 6*d.* net each.—The contents of this number are: 1. A Clinical and Pathological Study of the Heart in Diphtheria, by William E. Hume and S. J. Clegg. The forms of arrhythmia observed in cases of diphtheria have been submitted to systematic study with the polygraph and some interesting results have been obtained. It is asserted that any form of arrhythmia except sinus arrhythmia occurring in diphtheria indicates that the heart muscle or its nerves are involved in a pathological process, and it is urged that special precautions are necessary to keep the patient recumbent. The paper is illustrated by two interesting plates. 2. The Effects of Anæmia upon the Pathological Processes Occurring in Acute Ulcer of the Stomach, by C. Bolton. From clinical and experimental observations it would appear that the anæmia induced by direct loss of blood has no influence as an isolated factor in facilitating the production of a gastric ulcer and none in causing its extension, nor does it prevent its healing. Two interesting plates accompany this paper. 3. Conduction in the Auricles, by A. E. Naish. A case of acute heart block is recorded with tracings which seem to admit only of the explanation that the cardiac impulse spreads to the ventricle and to the auricle by different paths, and does not pass to the ventricle through the auricle as hitherto supposed. 4. Observations on Inspiratory Diminution of the Pulse (Pulsus Paradoxus), by A. W. Falconer and James M. McQueen. Some interesting observations are recorded upon two healthy adult males who presented this condition. The authors bring forward evidence which tends to show that this alteration of the pulse in their cases followed on oval deformation of the third part of the subclavian artery due to muscular action involved in putting back the shoulders. They review the opinions which have been expressed as to the explanation of this condition when it occurs in other than healthy subjects, in which the one common factor appears to be an embarrassment of the circulation, and they suggest that the normal inspiratory diminution of blood pressure exaggerated by an abnormally low blood pressure is a sufficient explanation. 5. Pathological Changes in the Adrenal Glands, by T. R. Elliott. As a result of a large series of observations it is stated that there is no proof that the store of adrenalin in the medulla of the glands is increased in any disease. It is lessened in many infective diseases, and markedly so in cases of afebrile acute cardiac failure associated with mental distress in the struggle to live. The lipoid of the cortex is stored and lost under conditions entirely different from those which govern the other fats of the body. It does not disappear in emaciation but vanishes with great rapidity in acute febrile affections. Three good coloured plates are attached to this paper. 6. The Tonicity of the Abdominal Muscles in Enteric Fever, by Adam Patrick. Observations were made on the state of the abdominal muscles in a series of 55 male cases admitted to hospital with enteric fever. More or less generalised superficial resistance was found in 19 cases at some stage of the disease, usually early. Resistance was observed in a horizontal band in 14 cases. In 11 of these 33 cases there was no resistance in the right hypochondrium, but this was observed in 32 of the whole series of cases. It is suggested that the superficial resistance is connected in some way with the ulceration of the intestine.

The Indian Journal of Medical Research. Vol. II., No. 1.—This is an exceptionally interesting and instructive number of the journal, which at all times contains material of the highest scientific and practical value contributed by the officers of the Indian Medical Service. The issue before us comprises 16 original articles, and extends to more than 400 pages of printed matter, along with some 60 plates, many of which are coloured. In a short preliminary editorial the fact is mentioned, among other things, that Dr. R. Row, of Bombay, has succeeded in obtaining a culture of Leishmania donovani from the peripheral blood of a kala-azar patient.—Major E. D. W. Greig, I.M.S., who has been on special duty in connexion with the recent official cholera inquiry, furnishes two articles, the first of which deals with the invasion of the tissues by the cholera organism, with further observations on pneumonia in cholera cases. It gives details of the complete bacteriological examination of the organs of some patients made shortly after death had occurred. In the second paper, which is illustrated by a number of plates, Major Greig describes the lesions of the gall-bladder and biliary passages in cholera, giving a bacteriological, histological, and experimental study of the subject. In discussing the mode of entry of the cholera bacillus into the biliary tracts he states that this probably occurs in more ways than one. In some instances it enters from the intestinal tract, and the fact that the lesions have been traced to the point of entrance of the common bile duct into the duodenum seems to indicate this possibility. It has been shown, too, that the comma bacillus passes from the intestinal canal to the lymphatic glands and thence is distributed to the various organs. The cholera vibrios may also reach the liver and bile through the lymph channels. Up to the present Major Greig has not been able to cultivate the cholera organism from the circulating blood during life, so that it appears that the lymph channel plays a more important part than the blood stream in the distribution of the vibrios in cholera cases. Major Greig's study goes some way to supply a scientific explanation of the mechanism of the production of cholera carriers.—Captain Hugh W. Acton and Captain R. Knowles, directors of the Pasteur Institute of India, have been engaged in testing experimentally the efficacy of a number of remedies against snake bites, and in a contribution entitled "Studies on the Treatment of Snake Bite," divided into three parts and extending to 100 pages of the journal, they discuss the relative virulence of various snake venoms. The common cobra is regarded by them as the most poisonous snake in India. The value of certain remedial measures is considered, such as ligature, artificial respiration, compression of the bitten limb, excision of the bitten area, amputation, &c. The relative value of well-known local remedies is also discussed, including potassium permanganate, iodine trichloride, and gold chloride.—In another article dealing with this subject Surgeon-General W. B. Bannerman reports on the treatment of snake bite with potassium permanganate, giving details of a series of animal experiments.—Two papers are contributed by Major R. McCarrison on the subject of goitre,[1] the first relating to the pathogenesis of experimentally produced goitre and the second describing some experimental researches on the etiology of the endemic form of the disease. Both of these articles are illustrated by numerous plates. The same investigator adds a contribution to the study of experimental beri-beri.—Major S. P. James gives an interesting summary of a year's mosquito work in Colombo, and Captain Clifford A. Gill, chief malarial medical officer in the Punjab, describes an epidemic of fulminant malaria, together with a preliminary study of the part played by immunity in malaria.—Major A. C. McGilchrist furnishes the first part of a report on the Cinchona Derivatives Inquiry, showing the results of experiments with cinchonidine, quinine, cinchonine, and quinidine. In a second communication the same expert describes some further experiments on animals with other derivatives of cinchona, including ethyl-hydro-cupreine-hydrochloride, hydro-quinine-hydrochloride, and quinine hydrochloride.—The occurrence of stegomyia maculosa in Madras, together with some observations on its habits, is the title of a contribution by Captain W. S. Patton, who also supplies a short article on the behaviour of the parasite of Indian kala-azar in the dog-flea, ctenocephalus felis (Bouché), with some remarks on canine kala-azar and its relation to the human disease.—The classification of bacteria for the purposes of water analysis is discussed by Major J. W. Cornwall, of the Pasteur Institute of Southern India, and Major F. Percival Mackie gives a note on the parasite of bat malaria; he also furnishes a paper on a flagellate infection of sand-flies. The bursate nematodes from the Indian elephant are described, with many illustrative plates, by Major Clayton Lane. From this brief summary it will be seen that the contents of this number are particularly interesting.

ASYLUM REPORTS.

Kingseat Mental Hospital, Aberdeen (*Annual Report for the Year 1913*).—The total number of cases under treatment during the year was 592, the average daily number being 467. The direct admissions amounted to 110. Among the predisposing causes of insanity it was ascertained that 30 were hereditarily predisposed to nervous or mental affections, and that 22 had suffered from one or more previous attacks. The discharges during the year numbered 50, with a percentage of 27·2 of recoveries on the total admissions. This recovery rate was 10 per cent. lower than last year, and the decrease was due to the large number of incurable cases admitted. The majority of the patients discharged recovered suffered from the various forms of manic-depressive insanity. The deaths numbered 66, an increase of 12 over last year. Twenty-one of the patients who died were over 70 years of age. The chief causes of death were valvular disease of the heart, general paralysis, senile asthenia and exhaustion following attacks of manic-depressive insanity. There is at present no patient confined to bed with pulmonary tuberculosis, and no patient with that disease in an acute form. Dr. H. de M. Alexander, the medical superintendent, remarks that the adoption of the new villa type of asylum gives increased facilities for granting parole, and that this is its most valuable asset. Some patients who were discontented and perpetually railing against the supposed illegality of their detention have, on being granted parole, become contented and loyally disposed towards those whom previously they regarded with feelings of distrust and antagonism.

Northumberland County Lunatic Asylum, Morpeth (*Annual Report for the Year 1913*).—The total number of cases under treatment during the year was 1028, the average daily number on the register being 793. The number of direct admissions was 233 and of discharges 116. The recovery rate was 34·78 per cent. calculated on the total admissions. The deaths amounted to 111, making a percentage on the average number resident of 11·58 for the males and 17·42 for the females. This rate, especially for the women, must be regarded as high. Of the 111 deaths, 15 are attributed to general paralysis, 11 to epilepsy and other forms of brain disease, 12 to exhaustion from mania or melancholia, 29 to phthisis and other tuberculous diseases, 6 to colitis, and 16 to senile decay. Seventeen of the persons who died were 70 years of age or upwards. As illustrating the unfavourable nature of the cases sent here for treatment it may be noted that 13 died within the first month and 14 during the second month following admission. The death-rate from phthisis amounted to over 26 per cent. Dr. T. W. McDowall, the medical superintendent, calls attention to the fact that the asylum continues to be inconveniently crowded, and he considers that the want of adequate space for the sick and infirm is a cause of disease. He also speaks with great earnestness of the necessity of awakening interest in scientific research as to the cause and treatment of mental disease. Years of neglect of these higher views as to the care of the insane and the administration of asylums has brought the medical department of this work into bad repute with the medical profession, and at the present time it is almost impossible to get intelligent, keen young professional men to enter the service. Dr. McDowall urges the committee of the asylum to appoint a small subcommittee for investigation of this matter.

County Borough of West Ham Lunatic Asylum (*Annual Report for the Year 1913*).—The total number of cases under treatment during the year was 1234, the average daily number on the register being 973. Out of the 233 direct admissions, 61 cases had a hereditary history of insanity, epilepsy, alcoholism, or other neurosis, giving a percentage of 26. In 37 cases the existence of a greater or less degree of alcoholic intemperance was obtained, and mental stress in 11 cases. The other principal exciting causes were senility in 13 cases and puberty in 5 instances. Fifty-one cases were discharged recovered, giving a percentage of 21·8 on the direct admissions, and a percentage of 4·13 on the total number under treatment. Mr. L. F. Hanbury, the medical superintendent, points out that the comparatively low recovery rate is due firstly to the very hopeless class of patient usually admitted on the male side, and secondly to the fact that the standard of recovery is a high one. There were 117 deaths, giving a percentage of 9·49 on the average number resident—15·45 for males and 8·7 for females. General paralysis was the most frequent cause of death, occurring in 25·6 per cent. of the cases. Senile decay accounted for 20·5 per cent. Post-mortem examination was held in 87 per cent. of the deaths. Two patients died from dysentery, and in 11 cases tuberculosis of the lungs was regarded as either a primary or secondary cause of death. The provision of an open-air verandah on the male side has proved of great assistance both in the isolation and treatment of this disease, and similar benefit will doubtless be obtained from the one on the female side recently completed. The asylum continues to be greatly overcrowded.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 14, 1914.

The Lister Institute and the Medical Research Committee.

Nothing less than the future of the Lister Institute will be the subject of a discussion between the Members of the Institute on Wednesday next, Nov. 18th. The question at issue is whether the Institute should be presented to the nation, temporarily and on a trust basis, to be the headquarters of national medical research, amalgamating for that purpose with the National Medical Research Committee set up under the National Insurance Act, and the answer to the question is one which the Members will necessarily have difficulty in finding. Perhaps they will be able to take comfort from the fact that as they are strongly recommended by influential persons to take both courses neither course can be without its distinct merits.

The steps which have led up to the present critical position are as follows. About two years ago the National Health Insurance Commissioners decided to institute in London, under powers provided by the Act, a Central Institute of Medical Research. This being known, the Governing Body of the Lister Institute in March last recommended to the Members of the Institute that, provided they had the legal power, they should offer to the nation, under conditions to be considered, the whole organisation and resources of the Lister Institute as the nucleus of the new department of medical research. The recommendation was based upon information readily supplied by the Medical Research Committee, appointed under the Act, and was accompanied with provisions: "(1) that representation on the executive committee of the national scheme should adequately safeguard the interests of the Lister Institute; (2) that suitable employment for the large majority of the present staff should be provided; and (3) that details of the programme and of the budget of the national scheme should command the approval of the Governing Body (of the Institute)." That Governing Body was, moreover, advised that the Members in carrying out such a recommendation would be within their legal rights, while Viscount Iveagh, who in virtue of his magnificent contribution to the endowment of the Institute enjoys the right to veto any disposal of the Institute to which he might object, approved the recommendation, making one of the five with seats on the Governing Body who voted in its support. There was one dissentient vote and one abstainer. The copy of the resolution, thus arrived at, having been forwarded to the Medical Research Committee through Lord Moulton of Bank, chairman of that committee, whose sympathy had already been enlisted, subcommittees from each body were appointed to consider, without prejudice to the future action of either, whether amalgamation would be feasible and acceptable. The two committees drew up a scheme, embodying the terms of amalgamation which they were prepared to recommend to their respective authorities as satisfying the stipulations of both sides. The proposed scheme of amalgamation provided for the representation of the present Governing Body of the Lister Institute on the Medical Research Committee, for employment of the present staff of the Lister Institute and the maintenance of its name, and set out in detail the disposition of the combined research staffs, with suggestions for adjustment of salaries. The prospective budget showed that the amount to be contributed towards the new Central Institute from medical research funds would be £19,000, at any rate for the next two years, but, Lord Iveagh having generously offered to build upon the land adjacent to the Institute at Chelsea a Research Hospital of 50 beds, the upkeep of this institution would entail later an annual additional expenditure of not less than £5000.

This scheme of amalgamation was considered on July 17th of this year at a full meeting of the Governing Body of the Institute, and at the close of the sitting a resolution was moved and carried on a vote of five (Sir Henry Roscoe, Viscount Iveagh, Mr. J. Luard Pattisson, Professor E. H. Starling, and Sir William Osler) against two (Sir John Rose Bradford and Sir David Bruce) approving of amalgamation. At the same meeting the honorary treasurer of the Institute, Mr. Pattisson, was instructed to seek an interview with the Treasury as to the terms on which the funds and property of the Institute could be offered to the nation. That interview was held on July 27th, when the terms, provisionally agreed to, proposed to place the property of the Institute in the hands of three official trustees as an endowment of capital for the benefit of national medical research, the income to be regularly set to the credit of the Research Fund. The trustees were to have the power to realise and reinvest any of the funded investments in their trust, subject to the approval of the Minister of State in charge of the Insurance Act, and if such a course should be recommended by the Medical Research Committee: they could also realise any land or buildings in their trust, the realisations being placed to the credit of the trust, and being available for reinvestment in land, buildings, or other securities. With the approval of the Medical Research Committee and the responsible Minister they would also be empowered to use any portion of the funds in their hands for capital expenditure. The suggested clauses governing the custody of the funds of the Institute further allowed for cancelling the trust in the event of the Government diminishing its contribution to the Medical Research Fund or ceasing wholly to utilise the Institute or its endowment for medical research. In these contingencies the trustees, in consultation with the Royal Society and with Viscount IVEAGH or his successor in the title for the time being, would submit for the approval of a legal court a new scheme for appropriating the property to the furtherance of medical research. Provision for the maintenance of the work of the serum farm at Elstree was made, and the last clause would terminate the Trust in 20 years by handing over unconditionally to the Government for the purposes of national medical research the whole of the property included in the Trust.

On the passing of the resolution approving the scheme for amalgamation Sir JOHN ROSE BRADFORD, the chairman of the Governing Body of the Lister Institute, resigned his chairmanship and seat on the Governing Body, and he has stated publicly that he regarded the proposal, involving as it did the cessation of the activities of independent organisation and the centralising of pathological research under Parliamentary control, to be prejudicial to the interests of scientific research.[1] He has received whole-hearted support in his action from distinguished men of science working in various branches of research, while the majority on the Governing Body have put forth an able and frank statement controverting his view, which cannot fail to command close attention. The issue is with the Members, who have to decide whether they will uphold with the necessary proportion of votes the recommendation of their Governing Body, which also has the approval of Dr. C. J. MARTIN, the Director under whose superintendence the Institute has risen, as is claimed in the statement of the Governing Body, almost to the status of a national institute for medical research. Of the force of the arguments on either side there can be no doubt. The projected national scheme for medical research has very much the same programme and same ideals as the Lister Institute, and it is believed that coöperation would prevent overlapping and prove economical. The Lister Institute, moreover, would gain by amalgamation that access to hospital practice which some of their Members miss. On the other hand, the arguments for keeping the Institute free from Government control are not without force. Scientific research is largely concerned in the discoveries of rules, but a Government department might be tempted to lay down rules for discoveries—which would be fatal. We would prefer to see the Lister Institute preserve its independence; we believe that there is ample scope for the energies of both bodies working separately. But we are bound to admit that those who take the opposite side in the controversy have forcible arguments behind them, notably the argument of expediency. And expediency must be reckoned with.

◆

The National Council for Combating Venereal Diseases.

IT was considered, and most wisely, by the organisers of the movement for constituting a National Council for Combating Venereal Diseases, that the present position of the country, in the grip of a terrible war, should not be a bar to their energies. We agree wholly with their resolve to continue the work which they had begun, finding, indeed, that the existing national situation is one that particularly calls for the combating of venereal diseases.

The objects of the new body, which definitely came into existence at an inaugural meeting held on Wednesday last, are wide and simple. The National Council will aim, firstly, at giving the public accurate and enlightened information as to the prevalence of these diseases. Here they will find a public curiously divided into two camps—namely, first, those who appear to know nothing of the matter or to be indifferent to its importance; and, secondly, those who have been terrified by false or misunderstood evidence into believing that every other person in the streets, and most of the children who are born, are the victims of syphilis. It will be difficult work at the outset to arouse interest on one side and to allay unnecessary apprehension on the other, and the lessons that will have to be read to the public will need careful consideration. The necessity for early treatment is a point which the National Council will put in the front of their teaching, and as a corollary they will strive to promote greater facilities for the treatment of these diseases than now exist, and wider opportunities for medical practitioners to study them. It is notorious that, under the ill-management and prudery which still have power among us, the treatment of venereal diseases has been unsatisfactory in many respects, and even the knowledge of a large number of medical men has been desultory or acquired only by a disproportionate amount of pains, owing to the conditions not having become familiar to them in the ordinary course of a hospital training. The setting right of these matters the National Council are placing in the front of their programme, and by attempting also to disseminate a sound knowledge of the laws of life they are going to the root of the matter. For physiological ignorance is at the bottom of much of the prevalence and spread of venereal diseases. This it is, every whit as much as any feeling of shame, which sends the victim to a quack; devoid of the least knowledge of the significance of his symptoms he is willing to believe any audacious lie which he may read in an advertisement or any stupid counsel he may receive from an equally credulous friend. Physiological ignorance again allows the terrible results of latent infection to wreak themselves upon women and children, and still more strikingly is it apparent in the malignant teaching, once so common, that chastity is in most cases impossible and in many cases harmful.

---

[1] Brit. Med. Jour., August 1st, 1914, p. 265.

Following upon a wide spread of information to the public it will become possible for the National Council to promote such social and legislative reforms as are relative to the aims and objects of the movement. Here the National Council will attempt to coöperate with existing associations so that much excellent but disconnected effort may be utilised in a coöperative manner. For example, the Liverpool Medical Institution about a year ago appointed a committee to consider the best means of combating venereal diseases, and this committee recommended that educational methods should be adopted in very much the manner that the National Council desire. Dr. CHARLES J. MACALISTER, the chairman of the committee, has written an admirable pamphlet for distribution to the public, which might well receive gratuitous circulation, while Dr. R. W. MACKENNA has added a warning to soldiers which is, in our opinion, extremely timely. "You are going," says the note to soldiers, "to fight in order that your children and your children's children may enjoy the heritage of liberty. See to it that no action of yours will rob them of a heritage that is as priceless as liberty—the heritage of good health." As the prevalence of venereal disease among the recruits has been referred to in our columns, we take this opportunity of saying that in many directions we have heard that the conditions have greatly improved.

Annotations.

"Ne quid nimis."

THE FUTURE OF MEDICINE.

REFORM in the methods of medical education seems to be everywhere in the air. In an address at the Jubilee of the Medical School of Melbourne University Dr. James W. Barrett, C.M.G., dealt with the problem particularly as it affects Australia. In the course of his remarks he made some observations of a general character. He pointed out that two great problems dominate the future of medicine: (1) clinical research; and (2) organisation of preventive medicine. With regard to the first, he suggested that the problem of pathology is the problem of medicine and *vice versâ*, and that investigations in both pursuits had better be undertaken by a man who is both a pathologist and a physician. It is the separation of what is called "pure science" from its human context that constitutes a fault. Our conception of the term science needs amending. Medicine and surgery are not the application of science to practical problems, but are divisions of science in themselves—that is to say, that from the study of phenomena principles can be inferred. Dr. Barrett advocates, more or less, the plan of the Johns Hopkins University, championed in this country by Professor E. H. Starling and Sir William Osler, that in the future in every great hospital there must be a physician and a surgeon devoting themselves entirely to the study of medicine and medical education, and relieved from the necessity for private practice. He considers it not undesirable that even the professors of physiology and anatomy should be permitted to do a certain amount of hospital clinical work, which would familiarise them with the necessary sense of the nature of the problem to be faced daily, and offer a continuous inducement to the professor to mould the teaching of his subject in accordance with practical suggestion. Some of the methods of chemistry, he thinks, could be taught equally well if the problems submitted to examination were those connected with the human body, healthy or diseased. The professors would thus be stimulated to devote their leisure to research more directly connected with the work of the physician and the surgeon. Dr. Barrett advocates the creation of an organised system of preventive medicine which shall include all the present scattered sanitary agencies, beginning with the school medical work and taking charge of the public health in all its ramifications. A Central Board of Health, he urges, should be instituted, to include one or two representative medical men, in addition to the chairman, an engineer, an architect, and perhaps one or two municipal representatives. The functions of such a board would be the general development of preventive medicine, the control of the medical health officers, and the establishment of by-laws and general regulations. No scheme of preventive medicine can be efficient unless the coöperation of the medical profession is secured, and that can only be effected by asking them to take a hand. Such a board would have to consider questions of town planning, housing, rural settlement and food-supplies, smoke abatement, and all those problems which are concerned in the consideration of a more complete and better enjoyment of life. It seems clear that medicine is passing more and more from its traditional individualistic standpoint and becoming increasingly corporate in its aims. In the not distant future there may be a general movement on the lines indicated by Dr. Barrett.

CAMBRIDGE UNIVERSITY AND THE BELGIAN UNIVERSITIES.

BELGIUM, a national martyr, has surely deserved well of this country especially, in every capacity of life. Great Britain has done well, but not one whit better than it were shame not to have done, in making it a national responsibility to take charge of those unfortunate expatriates who have suffered so terribly in behalf of Europe and herself. But besides food, clothing, and shelter for the body, the mind of the race must not be allowed to starve, and in this respect the University of Cambridge has extended a helping hand in offering sanctuary in her ancient academic halls to the expatriated professors and students of the Flemish universities. It was hoped that Louvain University would be able to transfer her corporate and official existence to Cambridge for the period of her exile; but as that proved impossible, steps have been taken for the formation of unofficial courses under Flemish professors to protect the students from the demoralising and dangerous consequences of enforced idleness—courses that shall afford systematic instruction on the lines of the

Belgian universities in accordance with the individual requirements of refugee students, so far as is possible with a necessarily incomplete Belgian teaching staff. The faculties of philosophy and letters and also those of law and engineering are fairly well represented by several Belgian professors and students. Those of medicine and science are at present less adequate, but they are constantly growing. Eleven Belgian professors (of whom only one, Professor Van Gehuchten, with his interne, Dr. Arian, represents the faculty of medicine) are at present established in Cambridge, and three more are known to be coming, and it is hoped by their aid to organise teaching in the respective faculties, for which no fees will be charged. Facilities will also be afforded for those students with an adequate knowledge of English to attend the ordinary courses at the University, while classes for teaching English are at work and will be further extended as required. A hospitality committee, of which the secretary is Mrs. Verrall, at the Bureau de Renseignement, Trumpington-street, Cambridge, has been organised to assist those unable to meet the moderate charges of from 15*s.* to £1 a week for board and lodgings; but to be eligible for such assistance and for the free courses the students must submit themselves to a medical examination before the proper Belgian authorities and obtain a certificate that they are physically unfit for military service or have been rejected by the Belgian authorities for other reasons, while students of Belgian universities from foreign (neutral) countries must of course bear their own charges for maintenance. All applications should be made to Mr. J. T. Shepherd, King's College; or to Mr. E. Bullough, Caius College, Cambridge. It is earnestly to be hoped that in this way this country may be able in some degree to mitigate the effects of the vandalism wrought by our foes on true culture.

TRAUMATIC ENDOCARDITIS.

IT is well known that in severe injuries of the chest, such as are due to blows, falls, or crushing, rupture of the heart or pericardium or of the valves may occur, immediately producing symptoms. But it is not so well known that cardiac symptoms may be slight or absent, and develop later in consequence of endocarditis following the injury. In the *Boston Medical and Surgical Journal* of Oct. 1st Dr. S. G. Weber has reported the following case. On Dec. 24th, 1908, a strong boy, aged 16 years, was riding in a wagon with which an electric car collided. He remained unconscious for half an hour. He was bruised on the left side of the trunk, left arm, and left leg. He complained of pain in the head, shoulder, and back, and could not lie on the left side. Attacks of giddiness and faintness occurred three or four times a day for the first week, and these continued for six weeks, during which the breathing was difficult. About ten days after the accident he was taken to the Massachusetts General Hospital, where examination with the X rays showed separation of the upper epiphysis of the left humerus. Dr. Weber saw him on Feb. 9th, 1909, when he complained chiefly of pain in the back and left arm. There was tenderness above the left clavicle, over the cervical plexus and over the sixth to the eighth dorsal vertebræ. The heart sounds and area of dulness were normal. He was not seen again until September, 1912, when he was working as a teamster. He was a tall, fleshy, strong-looking man, but he could not lift heavy weights, and if he tried to he felt pain in the lower dorsal region. He could not run so well as before the accident and soon got out of breath. There was a loud systolic souffle over the whole præcordium, loudest at the edge of the sternum opposite the fourth rib. The impulse was in the seventh intercostal space, about half an inch to the right of the nipple. There was slight œdema of the legs. An explanation of the development of endocarditis some time after an injury is furnished by those cases of injury causing early death from lesions other than cardiac, in which slight lesions in the heart are found to be originating inflammatory changes. Riedinger mentions as one of these lesions small ecchymoses within the heart which may lead to changes in the valves similar to valvular lesions arising from other causes. He reports the case of a woman, aged 54 years, who fell from a third storey into the street and died three days later. There were fractures of the lumbar vertebræ and occiput. The endocardium showed a thin exudation and was infiltrated with blood. The points of insertion of the chordæ tendineæ into the mitral valve were swollen. Under the endocardium were many small hæmorrhages and spots of inflammatory infitration. Bernstein has collected and analysed 126 cases in which cardiac symptoms followed an injury. In 85 they appeared immediately, in 22 after a month, in 6 after a year, and in 9 after more than a year. The less severe injuries of the heart are slight lacerations of the muscle or ecchymoses into its substance or just beneath the endocardium. Any symptoms produced may soon disappear. But slow valvular changes may follow and be recognisable only after a longer or shorter time. Such slight cardiac injuries have been overlooked or ignored as causes of valvular disease.

NATHAN SMITH.

Nathan Smith,[1] though his name is little known in this country except to students of medical history, is one of the most important figures in the history of American medicine, especially as regards its educational side. He was the founder of the medical school of Dartmouth, New Hampshire, in 1798, the practical founder of the Yale Medical School in 1813, and the inaugurator (in conjunction with President Allen, of Bowdoin College, Brunswick, Maine) of the Medical College in connexion with Bowdoin, endowed by the Legislature of Maine in 1820. Finally, about 1821, in collaboration with his son Nathan Ryno Smith, he established the Medical School of the University of Vermont. Thus, with the addition of Harvard, five of the six New England States were provided with medical schools, and Nathan Smith's own opinion was that "every State should have one medical school and no more." Nathan Smith was a descendant of one of the old Puritan families who landed from the *Diligent* in New England in 1638. Among the settlers was a Mr. Henry Smith, who in process of time became Nathan Smith's great-great-grandfather. Henry Smith came from Hargham Hall, Norfolk, and so was presumably a country squire of the day. John Smith, Nathan's father, occupied himself in farming at Chester, Vt., and here Nathan passed his early days. He received his medical education from a well-known medical man in the same state, by name Goodhue, and studied with him from the age of 22 till 25, when in 1787 he set up on his own account. Most of the story of his life and work is told in his own words as given in his letters, and the interest of the book is much increased by the illustrations. Of Smith's medical writings the most notable are the Essay on Typhus (i.e., Typhoid) Fever and Observations on the Pathology and Treatment of Necrosis. His letters are delightful reading on account of their simple earnestness and desire for knowledge, and the whole book is well worth study.

THE CEREBRO-SPINAL FLUID IN ACUTE NEPHRITIS IN CHILDREN.

THE study of the cerebro-spinal fluid has at the present day acquired a paramount importance in pathology, due, in a large measure, to the numerous and interesting observations made on children who are without doubt the most fitting subjects for investigation, both from their proneness to disease of the central nervous system and from the ease with which lumbar puncture can be performed on them. In recent years this study has broadened its horizon in the fact that its importance is no longer limited to cases of affections of the nervous centres, but has extended also to morbid conditions not localised in them, and more especially at the present time to cases of renal lesions, with uræmia, acetonæmia, and azotæmia. From the fact that with regard to some substances, such as urea, for example, the cerebro-spinal fluid reflects more or less exactly the state of the blood serum, there being a parallelism between the amount contained in both these fluids, the utility of conducting investigations preferably on the cerebro-spinal fluid becomes evident. Professor L. M. Spolverini, of the University of Rome, estimates the presence of abnormally large quantities of urea, 1 to 4 per 1000 instead of 0·5 or 0·6 per 1000, as an indisputable index of a process of azotæmia, while a smaller amount excludes it absolutely. Authorities are not agreed as to the figures. Systematic researches in acute renal inflammation in children have hitherto been scanty, but Professor Spolverini gives in a recent issue of *Il Policlinico* the result of his investigations on four children, from 3 to 5 years old, two of whom had acute hæmorrhagic nephritis associated with angina, one an acute nephritis with malaria, and the fourth an acute nephritis of unknown origin. Lumbar puncture was practised in each on an average five to six times at intervals of three to four days, commencing from the second day of their admittance to the clinic. The fluid drawn off was found markedly increased in quantity, on an average 20–25 c.c. each time, and was under considerable tension. The amount was visibly diminished as the patient improved, but still remained rather excessive even after cure was established, as shown by examination of the urine. With regard to the quantity of urea in the cerebro-spinal fluid it was found to be increased in all the cases. Moreover, diminution in the amount was found to coincide with the clinical and anatomo-physiological improvement of the kidneys, and increase was noticed whenever retrogression was observed by examination of the urine. After recovery the quantity fell to 0·5 or 0·6 per 1000. The amount of chlorides remained constant both in the acute stage and after recovery, oscillating between the limits of 7·3 and 7·5 per 1000. Estimation of the amount of albumin gave similar results and was maintained within normal limits. Although the utility of these observations is limited on the one hand to the presence and degree of cerebro-spinal hyperidrosis and on the other to the determination of urea, it is evident that it may constitute an important element, both diagnostic and prognostic, especially when compared with the clinical course and with examination of the urine. It has been suggested by Nobécourt and others that when the amount of urea reaches 3 per 1000 the life of the patient is in imminent danger. Lumbar puncture, moreover, offers certain therapeutic advantages, and Professor Spolverini's experience is that the withdrawal of cerebro-spinal fluid in patients with nephritis not only shortens and modifies in a favourable way the further development of the disease, but must be considered an efficacious method of eliminating the nervous phenomena of uræmia, both by decompression of the cerebro-spinal column and by removing from the organism, and especially from the central nervous system, a highly toxic fluid. This result is observable by the fact that the characteristic headache of the patients disappears after lumbar puncture, and the same may be said of the coma and convulsions which contribute so materially in raising, especially in children, the rate of mortality.

THE ULTIMATE RESULTS OF SANATORIUM TREATMENT IN TUBERCULOSIS.

AT a meeting of the Medical Society of Copenhagen Professor Bang read a paper, freely illustrated by statistics, on the results of sanatorium treatment estimated many years after the patient's discharge. His paper, and the long discussion which followed, have been reported in *Hospitalstidende*. The many tables and statistical analyses displayed by Professor Bang provoked a lively discussion as to the merits of statistics in the estimation of sanatorium results, and he admitted that a detailed knowledge of each case is necessary for the judgment of sanatorium results by the standard of figures. One striking feature of his paper was the good prognosis which his figures indicated for working-class patients admitted to a sanatorium in the second and third stages of the disease. It has long been held that the prognosis in pulmonary tuberculosis is best in the first stage of the disease, and declines as the second and third stages are reached. Indeed, this view is so generally regarded as a truism that its accuracy has scarcely been questioned. That it does not embrace the whole truth is shown by Professor Bang, whose figures are obtained from several sanatoriums in Denmark, where, perhaps more than in any other country, sanatorium treatment has been thoroughly tested. The relative numbers of patients discharged "symptom-free" from sanatoriums do, indeed, fall with the stages of the disease; but when the fate of all the patients is investigated several years later many of the "symptom-free" are found to have relapsed, while patients discharged unimproved in the second and third stages of the disease are often found to have regained their capacity for work. Professor Bang showed that only two-thirds of the patients in the first stage, discharged as "symptom-free," were fit for work several years later. On the other hand, the number of patients in the second stage, discharged as "symptom-free," had actually been augmented several years later, their ranks being increased by one-third by patients who, though discharged as unfit for work in the second stage of the disease, had ultimately regained their capacity for work. This paradoxical result is even more striking in the third stage of the disease. The explanation of this phenomenon is to be found in the faultiness of the present classification of the disease according to its extent, but not according to its virulence, to the patient's power of resistance, and to many other factors. In many cases patients are classed in the second or third stages, although on admission to a sanatorium the disease is practically quiescent. Professor Bang suggests that the present tendency to favour patients in the first stage of the disease in preference to patients in the other stages when sanatorium accommodation is limited may not be always wise. Though the patients in the latter stages have hitherto been regarded as incurable and treated with scant attention, he urges that they should in the future be regarded more hopefully and given the chance of sanatorium treatment, even though this be only for a short time. His observation that patients often relapse who are discharged from a sanatorium with the disease arrested in its first stage, whereas others often recover who are discharged unimproved in the second stage, is not at first sight flattering to sanatorium treatment. His estimate of the value of the present methods of classification of the disease is also depreciatory, and, as one speaker during the discussion cannily suggested, the most reliable classification would be the following: (1) patients that recover, and (2) those that do not.

CONGENITAL PYLORIC STENOSIS.

Mr. A. J. Walton[1] recently had an opportunity of observing the condition of the pylorus post mortem, seven months after a completely successful operation, gastro-enterostomy, had been performed for this defect. Such an opportunity cannot often occur. Since the date of operation and up to a short time before death, due to epidemic diarrhœa, health was excellent; it might have been expected, therefore, that the pylorus would have to some extent resumed its normal form. This, however, was not the case. It formed a tumour-like mass, three-quarters of an inch in length. Section showed an enormous hypertrophy of the muscular coats and the mucosa was thrown into folds. It was impervious to the passage of water. Such an observation throws some doubt upon the view which regards congenital hypertrophic stenosis as essentially congenital, but is in favour of the condition being due to a primary spasm, which later is followed by pure hypertrophy of the muscle coat. A symptom which supports this view and which is characteristic of the condition is that the child at birth can retain its food; vomiting usually begins only when the maternal milk is changed, such alteration inducing by irritation the primary spasm. Treatment may be medical or surgical, and there are supporters to be found in both camps. Statistics are curiously variable as to the relative merits. Dr. G. F. Still reports 19 recoveries out of 36 cases treated medically. Four continental writers record between them 66 recoveries out of 71 cases similarly treated. On the contrary, Mr. Walton's personal experience gives startling figures for the physician: 18 died out of 19 cases (all hospital cases). Surgically the figures on the whole present successes in about an equal proportion to medically treated cases. The conclusion is suggested that medical treatment should be tried first. As to length of time Mr. Walton thinks for a space of two weeks only if the child still continues to lose weight, or three weeks if holding its own. Then surgical intervention should be indicated. Of medical treatment careful diet and lavage are the main features. Surgically, pyloroplasty or gastro-enterostomy is the best measure. The writer favours the latter method.

TREATMENT FOR NOCTURNAL ENURESIS.

Dr. Cahier has reported the results of a new form of treatment he has devised for nocturnal enuresis; it is applicable to either children or adults. He injects physiological salt solution at a rapid rate directly into the perineum, on each side of the median raphe. The quantity for an adult he places at from 80 to 100 c.c. on each side; for children 40 to 60 c.c. The skin must not be stretched unduly. The immediate result of the procedure, which is stated to be entirely harmless and comparatively simple, is to form a huge blister, and it is upon the effect of this on the nerve terminals in its vicinity that the curative value depends. The tension in the region when the desire for micturition occurs suffices to awaken the patient and aids in breaking the habit and re-establishing control. This method Dr. Cahier has tried upon 30 cases in the last eight years. In 18 there followed a complete cure after a single injection; in 6 a second or third injection was required; while in 6 no benefit was realised. By a similar method of treatment in children, Ganléjac reports 75 cures out of 150—half the number. Such results appear favourable and should warrant a further and more extensive trial.

IN connexion with the discussion on Surgical Experiences of the Present War, to be introduced by Sir Watson Cheyne, at the Medical Society of London on Monday next, Nov. 16th, at 8.30 P.M., the following have signified their intention of taking part: Sir Frederic Eve, Mr. Arthur Edmunds, Mr. R. P. Rowlands, Mr. D'Arcy Power, Mr. Charters Symonds, Dr. Dennis Embleton, and Dr. Ironside Bruce.

Surgeon-Major-General Sir John By Cole Reade, K.C.B., the Crimean veteran whose death at the age of 82 occurred recently in London, was the oldest of the Honorary Surgeons to the King. Some details of his distinguished career are given in our Service columns this week.

WE much regret to announce the death on Sunday last of Mr. Charles Barrett Lockwood, consulting surgeon to St. Bartholomew's Hospital, and a member of the Council of the Royal College of Surgeons of England.

THE PANAMA PACIFIC INTERNATIONAL EXPOSITION AT SAN FRANCISCO.—We referred to this exposition in THE LANCET of July 11th, p. 103. We now learn from the commission that notwithstanding any rumours of a postponement on account of the European war the exposition will be opened on the date previously announced—viz., Feb. 20th, 1915. The amount of money to be spent on the exposition has been carefully estimated at $56,500,000, "too vast a sum to be tied up and allowed to remain idle." The promoters expect every success to attend the project.

THE OCCURRENCE OF ACUTE EMPHYSEMATOUS GANGRENE (MALIGNANT ŒDEMA) IN WOUNDS RECEIVED IN THE WAR.

BY R. H. JOCELYN SWAN, M.S. LOND., F.R.C.S. ENG.;
ISAAC JONES, M.D. MELB.,
TEMPORARY LIEUTENANT, ROYAL ARMY MEDICAL CORPS; AND
J. W. McNEE, M.B., CH.B. GLASG.,
LIEUTENANT, ROYAL ARMY MEDICAL CORPS (SPECIAL RESERVE).
(*Attached to the Royal Herbert Hospital, Woolwich.*)

WE desire to place on record at once the following three cases of acute emphysematous gangrene which have occurred among the wounded sent home from the front. We do so in order to draw attention to the condition and to warn other surgeons in order that similar cases may be recognised and isolated at once from patients requiring surgical dressings. Although acute emphysematous gangrene was common in the pre-Listerian era, it has become a rarity since the introduction of antiseptic surgery.

Since the commencement of the war some 2000 cases have been admitted to the Royal Herbert Hospital, but the disease has only appeared in the last fortnight. Two of the cases were recognised immediately at the reception of the convoy, but the third case had been two days in hospital before the condition became manifest. The condition is, of course, unlikely to occur in moderately clean wounds, as the causal organism, being an anaerobe, develops better in the presence of other pyogenic organisms.

Diagnosis.

The three cases described below are all similar in the fact that in smears from the discharge spore-bearing organisms were found identical morphologically with the bacillus of malignant œdema. The spore-bearing bacillus did not grow aerobically, but was obtained in deep stab cultures in glucose agar from two of the cases. In the second case, in which amputation was performed, sloughing of the flaps occurred within 12 hours, and in the discharge the same spore-bearing bacillus was found present in almost pure culture. It was unfortunately impossible to carry out animal inoculations from any of the cases. The diagnosis of "malignant œdema" in these cases rests, however, as much on the clinical appearance as on the above bacteriological findings.

A description of the three cases is given briefly below, but emphasis may be given here to some of the important clinical points on which the diagnosis chiefly depends. These may be briefly summarised as follows: (1) The blackish-brown, almost charred appearance of the wound. (2) The abundance of a thin, brown-coloured serous discharge, in which microscopically much granular débris but comparatively few pus cells could be recognised. Great numbers of other pathogenic organisms were present in all three cases in addition to the spore-bearing bacilli. (3) The curious heavy, penetrating odour from the wound. (4) The skin surrounding the wound became of a slate-blue colour. Blisters containing brownish fluid were present over the area of dark skin in the case in which the gangrene had spread. (5) Fine emphysematous crepitations could be made out in the tissues surrounding the wound. (6) Marked toxæmia accompanied the disease in the two fatal cases, but it is noteworthy that in both of these consciousness was unimpaired until a minute or two before death.

Notes of Cases.

CASE 1.—Lieutenant H., wounded in the right thigh on Oct. 26th by a bullet fired at a range of five yards. The bullet entered the thigh posteriorly and to the outer side just above the knee, and passing out on the inner side of the thigh obliquely caused a wound about 8 inches in length. Wounded at 2 A.M., the patient was obliged to lie in the trenches until after midday, when he was carried in an old and dirty farm cart to the field hospital. He arrived at Woolwich on Oct. 29th looking pale and ill, with a temperature of 103·6° F. The wound on the inside of the thigh presented the appearance of a bayonet thrust, being 8 inches long and 3 inches broad at its widest part. It passed deeply into the muscles of the thigh and was very foul.

The patient was given an anæsthetic at once, and the whole wound was thoroughly opened. The cavity was swabbed out with hydrogen peroxide and then with solution of iodine, and afterwards a large fomentation was applied. On Oct. 31st he appeared much better, but at 11 P.M., when the wound was being dressed, it was noticed that the outer edge was slightly discoloured, and the surface of the wound had assumed a dark, charred appearance. His general condition grew rapidly worse; he had profuse sweatings, and became collapsed. At 6 A.M. on Nov. 1st the wound was quite black in colour, and discharging an enormous amount of thin brownish fluid. The thick dressings were soaked through by the abundance of the discharge. The outer and upper third of the thigh became livid and then dark blue in colour, and the epidermis became raised in places into blisters containing also a thin brownish fluid. Fine crepitations could now be felt in the tissues surrounding the wound.

The fluid discharge from the wound on examination was found to contain few pus cells and enormous numbers of organisms, including a spore-bearing bacillus identical morphologically with the bacillus of malignant œdema. The appearance of the wound and the characters of the discharge had completely altered in eight hours. The emphysematous process increased, and the patient died at 12.15 P.M.

CASE 2.—Belgian soldier, F. T., admitted on Nov. 2nd, 1914. He was wounded on Oct. 28th while scrambling out of a trench before the advancing Germans, and fell back into the trench. The bullet entered behind the right knee and came out in front. He was made prisoner, and lay for 26 hours in the trench before the French re-took the position, after which his wound was dressed for the first time. The wound was again dressed on the following day (Oct. 30th), but not again until admission to hospital at Woolwich. He was found to have a severe wound below and behind the right knee, shattering the head of the tibia and opening the knee-joint. The wound was lacerated, black in colour, and from it there exuded a thin dark-brown coloured fluid. Swelling and definite emphysema were present in the tissues surrounding the wound. The patient's general condition was bad. A bacteriological examination of the fluid made immediately after admission showed pus cells to be scanty and a considerable amount of granular débris. Organisms of many kinds were present, and also very numerous spore-bearing bacilli, identical morphologically with the bacillus of malignant œdema.

The patient was at once removed to an isolation ward, and the limb was amputated through the upper third of the thigh (Lieutenant Jones). The flaps were swabbed freely with hydrogen peroxide, and free drainage established in the stump. Within 12 hours, however, sloughing of the flaps set in, and in films from the discharge the spore-bearing bacillus was found. The organism was grown in glucose agar stabs in almost pure culture. The patient's general condition became worse, death occurring six days after the operation.

CASE 3.—Belgian soldier, F. L., admitted on Nov. 2nd, in the same convoy as Case 2. He was wounded on Oct. 28th by a rifle bullet fired from a range of 10 metres. He had 60 cartridges in his right trousers pocket, and states 15 of them exploded on being struck by the bullet. After being wounded the patient lay in the trenches for 24 hours a prisoner of the Germans, and was not dressed until 30 hours after his wound, when the French again occupied the position. Eighteen hours later he was again dressed at Calais.

Immediately after admission smears were made from the thin discharge from the wound and spore-bearing bacilli found to be present. The spores were central and the organisms identical morphologically with those of malignant œdema. There was, however, no local gangrene round the wound, but slight emphysema around the larger wound. The patient's general condition was quite good, and he was at once isolated. It was decided to treat the case by incising the area very freely, and this was done at once. Numerous small fragments of cartridge casing were taken out of the wound, which was well swabbed with hydrogen peroxide and potassium permanganate solution. The result has been good, and the patient is so far doing very well. His pulse and temperature are now normal, and his wound is becoming covered with healthy granulations.

Treatment.

Remarks on prophylactic treatment are here unnecessary, but it will be noticed that in each of the three cases the patients had in the exigencies of circumstances to remain lying in the trenches untreated for many hours. With the occurrence of the disease active measures must be adopted as soon as the bacteriological evidence is forthcoming, first to isolate the patient from other surgical cases and then to attack the wound. In the first case the condition was hopeless from the onset of the spreading gangrene, and in the second amputation well above the wound was performed at once owing to the extensive injury to the knee-joint. In the third case the patient's general condition was such that it was decided to attempt in the first place to save the limb, especially as any operation would have to be performed through infected tissue. When it can be carried out, free and extensive incisions into the area with thorough swabbing with peroxide of hydrogen and permanganate solution should be used, and we are inclined to recommend this in preference to pure carbolic acid, as we are dealing with anaerobic organisms. In our two cases dressings soaked with hydrogen peroxide were applied very frequently. At the same time large quantities of saline should be given by the rectum and by subcutaneous infusion.

"THE LANCET" HYGIENIC TESTS FOR GAS FIRES.

IT seems to be agreed in the practical gas-fire industry that the requirements which we have laid down in regard to the escape of combustion products from the gas fire into the room should be complied with. If it were not so there would not have been so many applications to us to apply the hygienic test to new models of fires, and it seems certain that the test has been very generally adopted. At all events it is rarely now that the models sent to us show any defect in this respect, and we have little doubt that the fires are submitted to the test by the makers themselves at the factory before they reach us. The present winter season therefore opens well with a supply of gas fires which have passed a test of hygienic efficiency. We are sure that the establishment of this standard will do much to make this convenient means of domestic heating popular.

Another series of gas fires was recently submitted to us for testing purposes by the Parkinson Stove Company, Limited, of 129, High Holborn, W.C. The description of the models was as follows: No. 1950 Congreve, No. 1931 Ratcliffe, No. 1933 Ratcliffe, No. 1942 Edmund, No. 1721 Pathan, and No. 1732 Spartan. These were all well designed and attractively finished fires, and not one of them showed the slightest escape of combustion products either when tested in the open, unattached to a chimney, or when unprovided with a flue or elbow. We regard these fires, therefore, as satisfactory from the hygienic point of view.

We have also received from the Davis Gas Stove Company, Limited, of Luton, and 60, Oxford-street, London, W., four types of their new barless gas fires named as follows: Apollo, Venus, Neptune, and Cupid. These all bear evidence of careful construction specially directed to securing hygienic conditions of working. These makers introduced the hygienic test known as the shadowgraph test, so that they took the initiative in excluding gas fires which did not satisfy this test. In other words, they commenced the movement for condemning gas fires which allowed combustion products to escape into the room. Under these circumstances it seemed superfluous to test their own models. However, it is interesting to record that THE LANCET hygienic test was found to confirm the findings of the shadowgraph test, the standard which they adopted. There was no leakage of combustion products from these gas fires even when unaided by an elbow or lengths of flue-pipe. The complete passage of the combustion products through the flue nozzle was demonstrated, and the process is automatic. The firm is much to be congratulated on its pioneer work.

MEDICAL MAYORS.—The following members of the medical profession have been elected or re-elected to the mayoral chair:—Mr. S. Hale Puckle, M.B., Ch.M. Edin. (Bishops Castle), re-elected; Mr. S. R Alexander, M.D. Lond. (Faversham), re-elected; Mr. John Gordon Gordon-Munn, M.D., C.M. Edin., F.R.S.E. (Norwich), Lord Mayor; Mr. R. Jones Evans, M.R.C.S. Eng., L.R.C.P. Lond. (Pwllheli), re-elected; and Mr. J. Parkinson Atkinson, M.D. Glasg. (Saffron Walden), re-elected. It may be noted that the Lord Mayor of Norwich is the first medical man to occupy that high municipal office, though Sir Peter Eade was mayor of that city and county in 1893.

A MAHARAJA AND HIS MEDICAL ATTENDANT.—At Mussoorie recently a rather curious action was tried in which certain arrangements made by a Maharaja in his will for medical attendance upon his surviving family formed the subject of dispute. The Maharaja had by his will directed that certain arrangements for medical attendance upon his family made by him with Colonel Rennie, R.A.M.C., should be continued after his death and directed, his executors "after the departure of Colonel Rennie from Mussoorie to make a similar arrangement with the successor in his business if recommended by him and approved by my said executors, and failing that with the civil surgeon for the time being of Mussoorie." Colonel Rennie disposed of his practice to Dr. G. T. Wrench, the plaintiff in the action, before going to England, and recommended him to the executors of the Maharaja, who had died a short time before, but the executors appointed the civil surgeon, Major Hutchinson, I.M.S., to attend the family of the deceased. The plaintiff contended that they were obliged to appoint him unless they could show a good reason for not doing so, and brought his action to obtain enforcement of the clause in the will. For the defence it was pleaded that the services of Colonel Rennie had been dispensed with before the Maharaja's death, but the court found upon the construction of certain letters and the other facts proved that Colonel Rennie was the medical attendant of the testator's family, if not of himself, at the time of his death. The court, however, held that the direction to the executors to appoint Colonel Rennie's successor subject to their approval did not amount to more than a recommendation, and that they need not give reasons if in their discretion they preferred to do otherwise or call the plaintiff before them and give him a hearing. On this ground the plaintiff's suit was dismissed with costs.

THE SERVICES.

Royal Naval Division.

The following appointment has been made on the Divisional Staff: Fleet-Surgeon Arthur Gaskell, Royal Navy, to be Assistant Director of Medical Services (dated Sept. 22nd).

Royal Navy Medical Service.

The undermentioned Staff-Surgeons have been promoted to the rank of Fleet-Surgeon in His Majesty's Fleet:—Dated Nov. 8th: John Boyan, William Henry Daw, Hugh Leigh Norris, Adrien Andrew Forrester, John Stoddart, James Aquilon Forrest, Warren Guy Westcott, Francis John Louis Philip McKenna, Fairman Rackham Mann, William Wallace Keir, Edward Charles Sawdy, Percy Hooper Bannister, Richard Sidney Osborne, Edward Oliver Bamford Carbery, John Kimber Raymond, and Henry Rule Gardner.

The undermentioned have been appointed Surgeons for temporary service in His Majesty's Fleet:—Herbert McMaster, Bevington S. Jones, Cecil William Fletcher Greenhill, John Douglas James Bruce, Walter Croker Poole White, Thomas Smith Harrison, Edwin Lawrence Sturdee, Gomer Williams, Harold Garrett Chaplin, Frederick Lancelot Duckworth, Frank Winter Lawson, Strangeman Davis Kilner, and William Graeme Robertson.

The following appointments have been notified:—Fleet-Surgeon: E. C. Ward to the *Victory*, additional. Temporary Surgeons: B. A. Playne, lent to the *Pembroke*, temporary; H. G. Chaplin and F. L. Duckworth to the *Victory;* F. W. Lawson, S. D. Kilner, and W. G. Robertson, all to the *Pembroke*, additional, for disposal; J. D. J. Bruce, C. W. F. Greenhill, and W. C. P. White to the *Victory*, additional, for Haslar Hospital; T. S. Harrison and E. L. Sturdee to the *Pembroke*, additional, for Chatham Hospital; and G. Williams to the *Vivid*, additional, for Plymouth Hospital.

Royal Naval Reserve.

Surgeon: C. S. Brewer, R.N.V.R., to the *Eagle.*

Army Medical Service.

Supernumerary Surgeon-General Sir David Bruce, C.B., is restored to the establishment (dated Nov. 1st).

Royal Army Medical Corps.

Supernumerary Major Sir Edward S. Worthington, M.V.O., is restored to the establishment (dated Oct. 15th).

The undermentioned are granted temporarily the honorary rank of Lieutenant-Colonel:—Dated Oct. 30th: Major H. R. Kenwood, Royal Army Medical Corps, Territorial Force, and John Robertson. Dated Nov. 5th: Lieutenant Arthur Stanley Woodwark.

Lieutenant James R. Hill, from the Reserve of Officers, to be Captain.

Joseph Dalrymple to be temporary Captain (dated Oct. 15th).

The undermentioned to be temporary Lieutenants:—Dated Sept. 23rd: William Parry Morgan. Dated Oct. 9th: Douglas Gordon Cheyne. Dated Oct. 10th: Francis Frederick Brown, Thomas William Ramsden Strode, James Aubrey Torrens, Thomas Alfred Peel, Edgar Alan Pearson, William John Nisbet, Michael John Murray, Newton Matthews, and Ernest William Adcock. Dated Oct. 14th: Magnus Ross Mackay. Dated Oct. 19th: John Edmund Cox, Herbert Thomas Retallack-Moloney, Arthur Frank Palmer, Percy John Chissell, and Cecil Hallworth Treadgold. Dated Oct. 20th: Claude Kingston. Dated Oct. 21st: Daniel Boylan, William Herbert Brown, Joseph Henry Campain, Gerald Cock, Victor Lindley Connolly, David Horace Collingham, Walter James Ignatius Dwyer, Sydney Herbert Gibson, John Charles Boileau Grant, Alexander Keith Hamilton, James Gilkison Higgins, Douglas Frederick Kennard, Charles Joseph Kelly, Thomas Jones Latham, Charles Gordon Holland Moore, Albert Guy Miller, Albert John McClure Chesney Morrison, Alexander Thomson McWhirter, Frederick George Norbury, John William O'Farrell, Patrick Joseph O'Reilly, John Alexander Pringle, Edmund George Chambers Price, David William Reid, Thomas Thomson Rankin, Percy Charles Raiment, John Torrance Weir Stewart, Alexander Stephen, Garnet Wolsley Twigg, Ronald Joseph Tennant Thornhill, Charles Henry Thompson, Henry Ashbourne Treadgold, George Hector Urquhart, Alfred William Weston, William Miller Will, John Joseph Walsh, Richard Williams, and William Stuart Milne. Dated Nov. 1st: Claude Gray Colyer, Horace Charles Colyer, Stanley Alfred Ridett, Charles Weller, Frederick William Broderick, and George Gilbert Timpson.

The undermentioned are granted temporary rank as follows whilst serving with the Red Cross Hospital, Netley:—Temporary Majors: Dated Oct. 27th: C. H. Miller and C. Wallace. Temporary Captains: Dated Oct. 27th: C. Christopherson, J. L. Dickie, J. A. Hayward, C. Hitch, H. L. Tidy, and A. C. Hudson. Temporary Lieutenants: Dated Oct. 27th: W. Anderson, M. S. Esler, J. G. Ferguson, C. Gibson, J. D. Lyle, J. F. Mackay, L. E. C. Norbury, and C. Pearson.

Special Reserve of Officers.

Royal Army Medical Corps.

The undermentioned Lieutenants to be Captains:—John Henry Bell, John Phethean Charnock, Harold Fitz Vallacott, and John James McIntosh Shaw.

The undermentioned Lieutenants are confirmed in their rank:—Maurice A. O'Callaghan, William Fotheringham, Archibald W. Russell, George A. Bridge, Archibald J. Gilchrist, Eric K. Ryan, John W. Cannon, Charles A. McGuire, Herbert M. Pope, William T. Quinlan, Edward B. Marsh, James McCusker, Leonard J. Sheil, William F. Wood, Adiel E. H. Reid, and Verner Wiley.

Supplementary to Regular Units or Corps.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank:—Alexander Keith Robb and Thomas Clifford Owen.

The undermentioned to be Lieutenants (on probation):—Henry Alcock, John Kennedy, and Thomas Fuller Kennedy.

Territorial Force.

Royal Army Medical Corps.

2nd South Midland Mounted Brigade Field Ambulance: George Augustus Auden to be Lieutenant.

South-Eastern Mounted Brigade Field Ambulance: Captain Frederick B. Treves to be Major.

1st East Anglian Field Ambulance: To be Lieutenants: Alfred Errol Delgado and James Llewellyn Montfort Symns.

3rd East Anglian Field Ambulance: William Thomson Crawford to be Lieutenant.

1st Home Counties Field Ambulance: Arthur Maude to be Lieutenant. John Samuel Hudson to be Captain (temporary).

1st West Lancashire Field Ambulance: Lieutenant Harold Seddon, from Attached to Units other than Medical Units, to be Lieutenant.

1st Wessex Field Ambulance: Lieutenant Alfred J. H. Iles, from the Wessex Clearing Hospital, to be Lieutenant.

3rd Southern General Hospital: Captain Henry M. Clarke is seconded.

Eastern Mounted Brigade Field Ambulance: Basil Fawssett to be Lieutenant.

1st London (City of London) Field Ambulance: Archibald Leitch to be Lieutenant.

3rd London (City of London) Field Ambulance: Kenneth Vickerman Smith to be Lieutenant.

3rd Highland Field Ambulance: The undermentioned to be Lieutenants: Frederick Charles Chandler and George MacLeod Levack.

4th London Field Ambulance: Lionel Glover Pearson to be Lieutenant.

2nd South Midland Field Ambulance: Lieutenant-Colonel Seymour G. Barling, from the South Midland Clearing Hospital, to be Lieutenant-Colonel. Captain Alfred A. Hingston, from Attached to Units other than Medical Units, to be Major.

3rd Welsh Field Ambulance: Lieutenant-Colonel Arthur Lloyd Jones resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform.

3rd Wessex Field Ambulance: Charles Henry Maskew to be Lieutenant.

1st London (City of London) Sanitary Company: Captain Joseph Grounds to be Major (temporary). Lieutenant Evelyn C. Sprawson to be Captain (temporary). Lieutenant Arthur T. Pitts to be Captain (temporary).

Attached to Units other than Medical Units.—Captain William A. Malcolm to be Major. To be Lieutenants: Arthur Scott Turner (late Lieutenant, 2nd Volunteer Battalion, The East Surrey Regiment), Robert George McDonald Ladell, and Cadet Arthur Henry Pemberton, from the London University Contingent, Senior Division, Officers Training Corps.

Deaths in the Services.

Surgeon-Major-General Sir John By Cole Reade, K.C.B. (A.M.S., retired), at Coleherne-road, Earl's Court, recently, in his 83rd year. He entered the Army Medical Department in 1854, and reached the rank of surgeon-general in 1888. He was present at the battles of Alma and Inkerman, and at the assaults on Redan and the siege of Sebastopol, where he was wounded (medal with three clasps and the Turkish medal), and he also served in the Indian Mutiny, being present at the siege and capture of Lucknow. In the Afghan war (1878–80) he was present at the entry into Kandahar (mentioned in despatches). For several years he acted as assistant to the Director-General of the Army Medical Department. He was appointed Honorary Surgeon to Queen Victoria in 1895, and was awarded the Jubilee Medal in 1897 and the Coronation Medals in 1902 and 1911. In 1892 he was granted the reward for distinguished and meritorious service. Sir John Reade, who retired in 1893, was the oldest honorary surgeon to the King.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8457 births and 4664 deaths were registered during the week ended Saturday, Nov. 7th. The annual rate of mortality in these towns, which had been 13·4, 13·8, and 13·5 per 1000 in the three preceding weeks, declined in the week under notice to 13·4 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 13·6, against 14·1 per 1000 in the metropolis. Among the several towns the death-rate last week ranged from 4·4 in Southend-on-Sea, 5·1 in Gloucester, 5·6 in Eastbourne, 5·7 in East Ham, 6·0 in Exeter, to 18·9 in Salford, 20·1 in Gateshead, 20·2 in Merthyr Tydfil, 21·1 in Liverpool, and 23·1 in Dudley.

The 4664 deaths from all causes were 44 fewer than the number in the previous week, and included 497 which were referred to the principal epidemic diseases, against 540 and 472 in the two preceding weeks. Of these 497 deaths, 169 resulted from infantile diarrhœal diseases, 146 from measles, 93 from diphtheria, 38 from whooping-cough, 34 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was 1·4 per 1000, and was equal to the rate in the previous week. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had steadily declined from 1223 to 204 in the seven preceding weeks, further fell to 169 last week, and included 49 in London, 16 in Liverpool, 11 in Birmingham, 10 in Manchester, and 6 in Sheffield. The deaths referred to measles, which had been 67, 101, and 123 in the three preceding weeks, further rose to 146 last week, and caused the highest annual death-rate of 1·2 in Liverpool and in Leeds, 1·3 in Preston, 1·4 in Plymouth, 1·7 in Oldham, 2·0 in Wakefield, 2·7 in Grimsby, 3·2 in Newcastle-on-Tyne, and 3·4 in Wigan. The fatal cases of diphtheria, which had been 59, 79, and 61 in the three preceding weeks, rose to 93 last week, of which 24 occurred in London, 10 in Birmingham, 5 in Wakefield, and 3 each in Walthamstow, Portsmouth, Bristol, and Middlesbrough. The deaths attributed to whooping-cough, which had declined from 50 to 32 in the five preceding weeks, rose to 38 last week, and included 6 in London, 4 in Newcastle-on-Tyne, 3 each in Leeds and Rhondda, and 2 each in Liverpool and Burnley. The deaths referred to scarlet fever, which had been 29, 37, and 38 in the three preceding weeks, fell to 34 last week, of which 6 were registered in London, 3 in Liverpool, and 2 each in Dudley, Salford, and Newport (Mon.). The fatal cases of enteric fever, which had been 14, 19, and 14 in the three preceding weeks, rose to 17 last week, and included 3 each in London and Hull, and 2 in Leeds.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 4683 in the 11 preceding weeks, had further risen to 4769 on Saturday last; 690 new cases were admitted during the week, against 650, 657, and 598 in the three preceding weeks. These hospitals also contained on Saturday last 1525 cases of diphtheria, 74 of enteric fever, 57 of whooping-cough, and 55 of measles, but not one of small-pox. The 1202 deaths from all causes in London were 22 fewer than the number in the previous week, and corresponded to an annual death-rate of 13·9 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 110 to 197 in the seven preceding weeks, fell to 193 in the week under notice, and were 14 below the number registered in the corresponding week of last year.

Of the 4664 deaths from all causes in the 97 towns, 213 resulted from different forms of violence and 369 were the subject of coroners' inquests, while 1444 occurred in public institutions. The causes of 28, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 76 other smaller towns. Of the 28 uncertified causes of death, 9 were registered in Liverpool, 5 in Birmingham, and 2 each in Preston and Tynemouth.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1140 births and 696 deaths were registered during the week ended Saturday, Nov. 7th. The annual rate of mortality in these towns, which had been 14·7, 15·0, and 14·6 per 1000 in the three preceding weeks, rose to 15·8 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 15·2, against 13·6 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 8·1 in Hamilton, 10·1 in Motherwell, and 11·7 in Clydebank, to 18·7 in Greenock, 19·0 in Leith, and 20·0 in Aberdeen.

The 696 deaths from all causes were 56 in excess of the number in the previous week, and included 79 which were referred to the principal epidemic diseases, against numbers declining from 96 to 78 in the four preceding weeks. Of these 79 deaths, 24 resulted from infantile diarrhœal diseases, 18 from diphtheria, 17 from scarlet fever, 12 from whooping-cough, 5 from measles, and 3 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against 1·4 per 1000 in the 97 large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 29, 31, and 26 in the three preceding weeks, further declined to 24 last week, of which 13 were registered in Glasgow, 3 in Dundee, and 3 in Aberdeen. The deaths referred to diphtheria, which had been 19, 19, and 16 in the three preceding weeks, rose to 18 last week, and included 7 in Aberdeen, 4 in Glasgow, and 2 in Edinburgh. The fatal cases of scarlet fever, which had been 16, 16, and 14 in the three preceding weeks, rose to 17 last week, of which 7 occurred in Glasgow and 7 in Aberdeen. The deaths attributed to whooping-cough, which had been 10, 9, and 14 in the three preceding weeks, fell to 12 last week, and included 9 in Glasgow. The 5 deaths referred to measles were all recorded in Glasgow, and were slightly in excess of the average in recent weeks. The fatal cases of enteric fever occurred in Dundee, Perth, and Coatbridge.

The deaths referred to diseases of the respiratory system, which had steadily increased from 62 to 92 in the seven preceding weeks, further rose to 104 in the week under notice; 30 deaths were attributed to different forms of violence, against numbers declining from 29 to 17 in the three preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 597 births and 420 deaths were registered during the week ended Saturday, Nov. 7th. The annual rate of mortality in these towns, which had been 16·2, 15·8, and 15·2 per 1000 in the three preceding weeks, rose to 18·2 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 16·2, against corresponding rates of 13·6 and 15·2 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 18·0 in Dublin (against 13·9 in London and 16·3 in Glasgow), 19·2 in Belfast, 19·7 in Cork, 14·0 in Londonderry, 17·6 in Limerick, and 36·1 in Waterford, while in the 21 smaller towns the mean death-rate was 14·7 per 1000.

The 420 deaths from all causes were 68 in excess of the number in the previous week, and included 48 which were referred to the principal epidemic diseases, against 44 and 51 in the two preceding weeks. Of these 48 deaths, 21 resulted from infantile diarrhœal diseases, 11 from measles, 6 from scarlet fever, 6 from whooping-cough, 3 from enteric fever, and 1 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·1, against corresponding rates of 1·4 and 1·8 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had steadily declined from 74 to 19 in the seven preceding weeks, rose to 21 last week, and included 10 in Dublin and 9 in Belfast. The deaths referred to measles, which had been 7 in each of the three preceding weeks, rose to 11 last weeks, and comprised 10 in Belfast and 1 in Cork. The fatal cases of scarlet fever, which had been 7, 5, and 12 in the three preceding weeks, fell to 6 last week, of which 5 occurred in Waterford and 1 in Belfast. The deaths attributed to whooping-cough, which had been 3, 9. and 4 in the three preceding weeks, rose to 6 last week, and comprised 3 in Belfast, 2 in Cork, and 1 in Dublin. The 3 deaths referred to enteric fever, of which 2 occurred in Dublin and 1 in Belfast, were equal to the average in the three preceding weeks. The fatal case of diphtheria was registered in Dublin.

The deaths referred to diseases of the respiratory system, which had been 71, 60, and 61 in the three preceding weeks, rose to 86 in the week under notice. Of the 420 deaths from all causes, 131, or 30 per cent., occurred in public institutions, and 9 resulted from different forms of violence. The causes of 17, or 4·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes did not exceed 0·6 per cent.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Canada and the War.

EVERYWHERE Canada feels the war. Doctors have forsaken good positions as medical officers of health to join their regiments, professors in the medical departments have already gone, also hospital superintendents. University corps are being rapidly established and trained. One notable professor has even joined one of these as a private—Professor J. George Adami. Schools of instruction in field ambulance and field hospital work have been established by the Government. The editor of the *Canadian Medical Association Journal*, Dr. Andrew Macphail, Montreal, has been taking this course of instruction in Toronto, along with a large class of civilian practitioners. Dr. Charles A. Hodgetts, medical adviser to the Canadian Conservation Commission, has been appointed Commissioner in Britain for the Canadian branch of the Red Cross Society, succeeding the late Colonel Burland of Montreal. The Director-General of the Canadian Army Medical Services, Colonel Carleton Jones, is with the Canadian Expeditionary Force; also Major Lorne Drum, general secretary of the Canadian Public Health Association, thus necessitating the cancellation of the annual meeting of this society, which was to have been held in Fort William and Fort Arthur in September. Medical societies in the leading centres have all contributed round sums to the Canadian Patriotic Fund. They have also pledged themselves to look after the practices of their *confrères* who have enlisted for service. They early put themselves on record as eager and anxious to care for the health of dependent ones of those qualifying for the front. Committees have been organised to look after the scarcity of drugs, and interest is being taken in the suspension of the Canadian rights of German patents in the pharmaceutical line. There are rifle clubs and home guards organised in every city and town. Shooting is being practised from premiers down. In fact, wherever one turns activities are observed in training, drilling, shooting, and the provision of relief for those at the front or their dependents. Thus it has been abundantly demonstrated that whenever England is at war Canada is at war.

The Canadians and Antityphoid Vaccination.

Whilst in camp at Valcartier, Quebec, the first Canadian Expeditionary Force were subjected to antityphoid inoculation. This was in charge of Dr. Charles A. Hodgetts, of Ottawa, and he was assisted by Dr. T. A. Lomer, medical officer of health, Ottawa; Dr. Campbell Laidlaw, pathologist, Ottawa General Hospital; Dr. Harry Morrell, pathologist, Regina General Hospital; and Dr. R. Woodhouse, medical officer of health, Fort William. The vaccine used was prepared in the laboratory of the Ontario Board of Health (presented by the Ontario Government), and was made up so that 1 c.c. equalled 500 million bacteria. The technique was simple, consisting in the application of the tincture of iodine over the injection area, followed by the injection. A second dose was administered in ten days of double strength. In the series of 45,000 injections probably the largest on record in the limited space of time, no severe cases of constitutional reactions were reported, though it was noticed during wet and cold weather the symptom of reaction was more pronounced than on dry and warm days.

Manitoba Sanatorium for Consumptives.

This institution was established in 1910 and in 1911, the first whole year, there were 168 patients admitted. In 1912 the number was 189; in 1913, 232; the admissions increasing largely in two years. The original policy of the hospital of admitting early cases only has never been adhered to because this sanatorium and the King Edward Hospital at Winnipeg being the only two institutions for the care of tuberculosis patients in Manitoba, they had to care for the entire field. The King Edward is a municipal hospital and cares for the advanced cases of the municipality of Winnipeg. The usual hygieno-dietetic means of treatment have been employed, artificial pneumothorax not having been used, but in suitable cases it will be used in the present year. In the year 1912 there were 492 deaths from tuberculosis in Manitoba, the totals running from 1909 to 1912 as follows: 402, 412, 438, and 492. Of the total deaths from all causes in Manitoba in 1912, the 492 cases of tuberculosis represented 8·5 per cent.—103·8 in 100,000 persons living. It is estimated that there are in the province 1800 cases. The 492 deaths were divided as follows: Pulmonary, 388; acute miliary, 7; meningitis, 54; abdominal disease, 25; Pott's disease, 6; white swelling, 2; tuberculosis of other organs, 7; and disseminated tuberculosis, 3. On Jan. 1st, 1913, there were 67 patients in the sanatorium—32 males and 35 females. There were 232 patients admitted during the year, 119 males and 113 females; and 203 patients were discharged—102 males and 101 females. 96 patients remained on Jan. 1st, 1914—49 males and 47 females. The total number admitted since the opening of the institution in June, 1910, was 686. On admission 2 were found non-tuberculous, 34 incipient, 52 moderately advanced, and 42 apparently hopeless. On discharge there were 3 not treated, 17 apparently cured, 58 quiescent, 70 improved, and 31 unimproved; 24 died. All save one of those classed as apparently hopeless on admission died.

Medical Inspection of Schools in Ontario.

The Education Department of the Province of Ontario has just issued a new code of regulations for the medical inspections of schools throughout that province. It is embodied in book form. It provides for one school board or a number of boards acting together to make provision for free medical treatment for pupils whose parents are unable to pay, and gives power to these boards to appoint a school medical inspection committee representing all boards. These committees must appoint a qualified medical practitioner of not less than two years' standing; but the medical officer of health of the municipality may be appointed with the consent of the Minister of Education and the Provincial Secretary, who has to do with all health matters in the province. The Act makes medical inspection compulsory in rural schools once every three months, in villages once a month, in towns once every two weeks, and in cities once a week. Provision is also made for the appointment of one or more nurses, and the medical inspector is subject to the school inspector or the principal. The medical inspectors are also required to act regarding the health of all children and conditions in schools as well as that in the home environment.

Toronto, Oct. 26th.

Correspondence.

"Audi alteram partem."

SIR JAMES Y. SIMPSON AND ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—I overlooked the courteous letter of Sir William Osler in THE LANCET of Oct. 31st correcting my reference to Sir James Y. Simpson as the discoverer of anæsthetics. The illustrious name of Simpson jumped to my mind in illustration of the point I wished to make, and at the moment I forgot that he had been anticipated with regard to ether. The interesting letter, again, of Dr. Leonard Guthrie in your issue of Nov. 7th corrects the Regius professor, and the two letters together are an additional exemplification of the point I wished to make that the discovery was due, was in the air, and focussed to practical usefulness almost simultaneously by several able experimenters. It seems incontestably shown by Dr. Marion Sims's article referred to by Dr. Guthrie that whereas nitrous oxide had been suggested as an anæsthetic by Sir Humphry Davy at the very commencement of the nineteenth century, the subsequent order of precedence in the discovery of various anæsthetics would seem to be Long (sulphuric ether) 1842, Wells (nitrous oxide) 1844, Morton (sulphuric ether) 1846, and Simpson (chloroform) 1847.

I still think that Simpson was the introducer of anæsthetics for general use in midwifery and in surgery, and it was not until his use of chloroform was established that disputes arose as to whom the reward of the discovery was due.

It is incidentally to be noted from the same source that the excitant properties of ether had been long known and utilised in America, and that on one occasion Dr. Wilhite had, in 1839, accidentally pushed the drug to the degree of extreme narcotism in the case of a negro.

I am, Sir, yours faithfully,

Portland-place, Nov. 9th, 1914. R. DOUGLAS POWELL.

THE SERUM DIAGNOSIS OF TUBERCLE BY THE FIXATION OF ALEXIN (COMPLEMENT).

To the Editor of THE LANCET.

SIR,—I have read with great interest the article by Dr. James McIntosh, Dr. Panl Fildes, and Dr. J. A. D. Radcliffe in THE LANCET of August 22nd last, but I regret to see that in the bibliography they have mentioned many German workers and have omitted Dr. W. d'Este Emery and myself, although THE LANCET published an article on this subject by myself on Dec. 31st, 1910, and by Dr. d'Este Emery in February, 1911. We worked independently, and we both found old tuberculin useless as an antigen.

In February, 1913, I sent THE LANCET an article on this subject. It was the outcome of two years' work and an experience derived from examining over 200 undoubted cases of tubercle and 100 normals and persons suffering from disease other than tubercle. As the article did not appear in THE LANCET I sent a copy to the *Indian Medical Gazette* in July, 1913, and it was published.

My technique is as follows:—

Antigen.—Human tubercle bacilli grown on glycerine veal broth, killed at 100° C., filtered, washed, and dried in vacuo. Half a grain is powdered very finely while dry in a watch glass with a glass rod till the particles become electrified by the friction. Thirty drops of 1 per cent. NaCl in ½ per cent. carbolic are then added, rubbing all the time. The whole of this is then transferred to a small tube, which is sealed with a piece of sealing-waxed paper; it is incubated for 24 hours, though 12 hours will suffice in an emergency. Three zones can now be distinguished—an upper opalescent, a central milky, and a third, clumps of bacilli. The two upper zones are pipetted off. This forms the antigen. It will keep for two or three days, but I prefer to use it only on the same day.

Serum.—40 c.mm. of fresh (i.e., not more than 36 hours old) patient's serum is placed in a small tube, this is heated in a water-bath to 52° C. for 15 minutes. I find 56° C. destroys some antibody. To this tube is now added 10 c.mm. of fresh serum (from the same patient), 10 c.mm. of antigen, and 250 c.mm. of 0·75 per cent. NaCl. A control of 10 c.mm. of fresh serum and 250 c.mm. of salt solution is also put up to show that complement is present. The tubes are now left at room temperature 60°-80° F. for one and a half hours or incubated at 98° F. for half an hour. Human alexin is very labile, and hence I found that incubation for one hour (when diluted) tends to destroy it. Sensitised goat's or sheep's red blood corpuscles are now added, 10 c.mm. of 5 per cent. emulsion. The corpuscles are well washed after sensitising, so as to remove all hæmolytic amboceptor. The tubes are now incubated for one hour and examined after all the cells have deposited (ice-chest over night or centrifuged). The slightest pink tinge is classed as doubtful; anything more than this is negative. With each batch, if possible, one or two normals should be put up; and until one is sure of one's technique, a known case of tubercle also. The only difficulty lies with the antigen; if it is found to fix the complement of normal serum, the bacilli in bulk should be well washed so as to remove anticomplementary substances (tissue extracts of the veal broth).

Note.—The proportion of tubercle antibody as compared to alexin in human serum is (except in chronic cases) as 1 to 4; hence the necessity of augmenting the antibody by using 4 parts of heated to 1 part of unheated serum.

I have examined serum from patients suffering from tubercle in almost every part of the body. I found the test most delicate in cases of lung, kidney, and spinal disease. When there is a small focus only—e.g., epididymis—I do not find the test delicate. In acute diseases of the lung the test fails, but as soon as the acuteness has abated the test comes off. Some normals occasionally give a positive result, but I have had very much fewer of these cases since rewashing the tubercle bacilli; but—and this is a very important point—a patient suffering from disease other than tubercle—e.g., appendicitis, pneumonia, abscess, osteomyelitis, &c.—shows a marked negative. My conclusions are as follows:—

1. This is a most delicate test for active tubercle, and is of great value in the diagnosis of the early stages of tubercle of the lung.

2. The tubercle antibody tends to disappear from the body very quickly. It is easily destroyed by heat, hence a temperature of 52° C. is preferable to 56° C. Human alexin is destroyed at 52° C. in 15 minutes.

3. Commercial tubercle bacilli may be used to prepare the antigen. As the tissue extracts in culture media contain substances which fix complement in normal serum, the bacilli should be washed if the antigen is found to be nonspecific. One knows that in doing an opsonic determination some brands of bacilli are useless till the emulsion has been washed in the same way as corpuscles are washed. The specific and active antigen appears to reside in the bodies of the bacilli, hence the necessity (especially if the bacilli have been well washed) of incubating the antigen for 24 hours. I do not find any reason to employ living bacilli. The nonspecific anticomplimentary substances appear to exist outside the bacteria (peptone, extractives, &c.)

4. A positive result can be relied upon when the patient is actually ill—i.e., losing weight, loss of appetite, fever, &c.; and when in the case of the lung there are even the faintest physical signs—e.g., impaired resonance in an apex, harsh

inspiration, &c. A positive result in health can be discounted.

5. A negative result can be relied upon if the patient is ill except in cases of very acute tubercle, when a positive result ensues later.

Fluctuation of the reaction.—In very acute tubercle the antibody cannot be detected; Dr. d'Este Emery also found this. In less acute it is present in a proportion of 1 to 4 compared with alexin; as the case progresses the proportion gradually increases to equal parts—i.e., 10 c.mm. of antigen will fix the complement in 10 c.mm. of fresh serum without the addition of any heated serum. As the case improves the antibodies pass off, till finally they can only be demonstrated by exercising the diseased organ or structure, or after subjecting it to passive congestion, or lighting it up by an injection of old tuberculin or peptone broth.

These latter measures give one a simple plan of further testing a case suspected to be tubercle, but giving a negative reaction.

As the first six months of this work was done in the inoculation laboratory at St. Mary's Hospital, London, W., most of the cases being Sir Almroth Wright's, I had, thanks to the kindness of Sir Almroth Wright, ample opportunity of comparing the two methods. My antigen and the tubercle emulsion used in the opsonic test are, except for the degree of dilution, the same; hence they must react on the same antibody.

I found that a low opsonic index went with a high immunity index, and *vice versâ*. This forces one to the conclusion that thermolabile opsonin is complement, and that the variations in the opsonic index are due to the absorption of complement during the incubation of the opsonic capillary tubes—i.e., the more the antibody present, the more the thermolabile opsonin absorbed. This is a very important consideration in treatment, for a lowering of the opsonic index should be the aim and not the dread. It further makes one reconsider the whole principle of the opsonic theory. I look upon a phagocytic index as only another means of demonstrating the Bordet-Gengou reaction.

As regards treatment by tuberculin, this test gives a laboratory demonstration of the poor value of tuberculin. Tuberculin is not an antigen to the true tubercle antibody; why, then, use it? In these days of autogenous vaccines I cannot understand why tuberculin has not long ago been discarded; I am inclined to think the reason is because it is a foreign introduction. I have found freshly prepared tubercle emulsion given in the same doses as tuberculin to be much more effective, but at present I am not in a position to state the case fully.—I am, Sir, yours faithfully,

V. B. Nesfield, F.R.C.S. Eng.,
Major, I.M.S.; late Chemical Examiner and Bacteriologist,
Government United Provinces, India.
Almora, U.P., Sept. 23rd, 1914.

THE LONDON PANEL COMMITTEE AND THE PRESCRIBING OF PANEL DOCTORS.

To the Editor of The Lancet.

Sir,—I have received a notice from the secretary of the London Panel Committee that they are, at the request of the Pharmaceutical Committee, making "investigations in respect of the drugs and appliances ordered by 65 practitioners during the period 12th to 30th April, 1914." I am then informed that, while for this period "the average cost of the prescriptions issued by all the practitioners on the panel was 9·7 pence," in my "individual case the average cost per prescription was nearly 1s. 1*d.*" I should like to dilate on the futility of an inquiry of this sort, in which no account is taken of the length of period for which medicine is supplied by each prescription; as a number of weekly prescriptions, costing, say, an average of 2*s.*, are a less demand on the drug fund than a correspondingly larger number of two-day prescriptions covering the same periods and costing an average of 9*d.* I should also like to know whether several prescriptions on one form, such as I am habitually writing, are counted as one or as many. In either case, by re-writing the prescriptions on new but more forms, and breaking them up, it would be perfectly easy, without at all altering the total amount prescribed, to reduce one's "average"—calculated in this absurd way—to almost any figure one wished.

But I am writing on a far more important matter which deeply concerns the other 64 practitioners alluded to. The Panel and Pharmaceutical Committees claim in this notice that they are carrying out the provisions of Article 40 of the Regulations of 1913. Now this article only empowers an "investigation" ...... "where it appears to the Panel Committee ...... that the cost of the supply of ...... the drugs or appliances ordered for insured persons ...... *is* in excess of what *may* reasonably *be* necessary for the adequate treatment of those persons"—that is to say, it authorises an investigation into prescriptions written for insured persons, to be made *while those persons are taking those prescriptions.* It cannot, therefore, apply to any inquiry into a number of prescriptions six months or more after the persons prescribed for have ceased to be under that treatment! Even if the wording of the article were not plain (which it is), common sense—which does not appear to be a strong point of the committees concerned—should show the impossibility of determining "what may reasonably be necessary for the adequate treatment" of anyone except when that person's ailment, symptoms, and idiosyncrasies (which, *pace* these Pharmaceutical and Panel Committees, even panel patients are human enough to have) can be actually examined and reported upon.

Another important point is that the Panel Committee are only empowered to "make a report to the (Insurance) Committee," on which alone the latter can act, "after hearing any practitioner concerned." Now no practitioner can be "heard" unless he voluntarily goes to the inquiry, and, when there, speaks. The Act and Regulations give the Panel Committee no power to compel him either to attend or to speak if he does attend, and yet no power to do anything without "hearing" him. I therefore advise my 64 brethren to reply, as I have done, that the "investigation" authorised by Article 40 is one to be undertaken during the treatment of the persons concerned, that this inquiry is therefore illegal, and that they must decline to give the Panel Committee the assistance of their presence, and will hold them legally responsible for any consequences that may ensue from their continuing to so conduct it. For my part, I welcome the "unsolicited testimonial" thus given me to the thoroughness of my treatment of my insured patients, for whom I, at all events, practically never order anything not in the British Pharmacopœia.

I am, Sir, yours faithfully,

Henry Bazett, M.A. Oxon., M.R.C.S. Eng.,
L.R.C.P. Lond.
St. Mary's-terrace, Paddington, Nov. 9th, 1914.

THE USE OF ALCOHOL ON THE BATTLE-FIELD AND ELSEWHERE.

To the Editor of THE LANCET.

SIR,—From one who may be supposed from constant association with the ill-effects of alcohol to be opposed to its use in any and every way, a few words may perhaps strengthen the eminently reasonable letter in THE LANCET of Oct. 10th of Dr. H. Lyon Smith on the above subject—reasonable because it is backed by personal scientific research which bears him out entirely.

My experience of many years' study of inebriety and inebriates leads me to uphold Dr. Lyon Smith's thesis. While there is, of course, no shadow of doubt that alcohol in toxic doses, or what amounts to the same thing in continuously taken moderate doses, acts harmfully on the animal organism, I have been unable to appreciate any harmful effects from a *strictly moderate* use of alcohol by persons of sound mental and physical health, such as our soldiers supposedly are. Dr. Mercier's statement that asylum observations show that insanity produces inebriety, rather than that inebriety produces insanity, as quoted by Dr. Lyon Smith, is undoubtedly a correct one. *Moderate* use of alcohol has never to my knowledge been proved to be a cause of insanity, but insanity in some degree may, I think, be said to be always present in true inebriety. What matters, not only on the battlefield but in everyday life, civil or military, is not that alcohol should be tabooed, but that it should be recognised by both the public and the medical profession as what it is—namely, a drug—one of the most powerful stimulant-narcotic drugs in the Pharmacopœia.

Dr. Lyon Smith has apparently satisfied himself that medicinal doses of 1½ to 2 oz. of whisky or other alcoholic liquor of like strength have a beneficial rather than a harmful effect on phagocytosis, so that it would be well unless those "scientific temperance lecturers" can prove the contrary that they should cease to use this argument against the use of alcohol except in so far as it applies to large doses, which neither Dr. Lyon Smith nor myself desires to defend or advocate. There appears to me to be only one danger of Dr. Lyon Smith's suggestion and advocacy in "emergency alcohol rations" for the troops—namely, that such rations might not, and I regret to say in all probability *would* not, be used with the same regard for dosage as other medicinal agents. This danger is, however, no argument against Dr. Lyon Smith's thesis, but for a better appreciation and knowledge of the actions and reactions of alcohol, such as would ensure a skilful and careful use of these rations.

The misuse and abuse of alcohol existing in this country in spite of "the wave of temperance which has gained much from the efforts of many distinguished members of our profession," is likely to continue until these distinguished members succeed in teaching, first our own *confrères* and through them the public that alcohol is a drug, not necessary or beneficial to the healthy individual, valuable in strictly moderate doses on occasion (by strictly moderate doses I mean from ½ to 2 oz. of good whisky, cognac, or gin), and extremely harmful in large or in frequently repeated small doses, exactly as is the case with other drugs of a similar nature—namely, the stimulant-narcotic group, and that, moreover, there are many more individuals than is generally supposed of such unstable psychophysical constitution as to be extremely susceptible to its toxic actions even in these extremely moderate doses, and that to these persons alcohol should without question be taboo.

I am, Sir, yours faithfully,

J. W. ASTLEY COOPER,
Medical Superintendent, Ghyllwoods Sanatorium for Treatment of Inebriety.

MEDICAL AUTOGRAPHS.

To the Editor of THE LANCET.

SIR,—The Reading Pathological Society has during many years collected in an album the autographs of distinguished medical practitioners, especially of such as have contributed to the progress of medicine, and are therefore "on fame's eternall bead-roll worthie to be fyled."

Such autographs, especially when accompanied by portraits, form a delightful addition to our knowledge of those personalities who are the *decus et desiderium medicinae*, and possess no small biographical and historical value. Medical societies will find in the formation of such an album a means of cementing the friendships of the living, and of perpetuating the memory of those who have passed beyond the veil.

Our collection already contains many interesting specimens of professional autographs, but further contributions (whether of British, American, or foreign origin) will be warmly welcomed.

I am, Sir, yours faithfully,

Westfield, Reading, Nov. 7th, 1914. JAMIESON B. HURRY.

PROGNOSIS IN CANCER OF THE TONGUE.

To the Editor of THE LANCET.

SIR,—Dr. Francis E. Shipway's letter in THE LANCET of Nov. 7th raises the important question whether the intratracheal administration of the anæsthetic or the administration of it through a temporary opening in the windpipe is the more satisfactory procedure in cases of cancer of the tongue. In an article under the above heading in your issue of Oct. 24th I had expressed a decided preference for the latter method. Dr. Shipway disagrees with my conclusion, and gives a number of arguments in favour of the intratracheal method.

I should like to state at once that I have no general objection whatever to Meltzer's procedure in cases where there is no ulcerating growth in the mouth or pharynx. I have done a number of operations under anæsthesia maintained in this way, and have been duly impressed by its many advantages. Again, I must express my satisfaction at finding myself in agreement with so authoritative an opinion as Dr. Shipway's as to the importance of a restricted airway in the causation of lung infections by aspiration. It is too often thought even now that, provided no serious grade of asphyxia is produced, a grossly obstructed airway has no importance, whereas a little consideration will make it obvious that obstruction increases the force with which foreign material from the mouth and pharynx is sucked into the air passages.

Dr. Shipway objects to a temporary opening of the windpipe as an addition to the length and severity of the operation. In cases of cancer of the tongue laryngotomy is practically always the operation of choice, tracheotomy being necessary only when the pharynx is involved and the opening has to be maintained for some days. Laryngotomy can invariably be done in a few minutes; if an ordinary bivalve tracheotomy tube be used the incision of the crico-thyroid membrane can be limited to the smallest puncture, so that the tube fits tight enough to prevent leakage of blood into the trachea and the opening closes very rapidly after the operation. In this way is avoided the most serious objection to the procedure—interference with the effectiveness of coughing. In my experience patients even when old and feeble settle down after the opening has been made into an extremely placid condition, in which they seem able to tolerate prolonged, extensive, and elaborate operations in a very remarkable way. I have no doubt that this relative immunity from shock is to a large extent due to the easy and quiet respiration.

With regard to the gland operation, which as I have shown may be followed by pneumonia if done as a preliminary to the removal of the primary growth, Dr. Shipway points out that either a preliminary laryngotomy must be done and repeated when the primary growth is dealt with, or the glands and the primary growth must be removed at the same time. I agree entirely with him that the latter alternative is usually undesirable, and would go so far as to say that it is often impossible. The former alternative—laryngotomy at each stage—is the method I generally use and one which gives very satisfactory results.

Turning now to the objections which I venture to think may be made to the intratracheal method, I should like to state quite definitely that in my view these apply solely to cases in which there is a foul ulcerating growth in the mouth. In cases where the growth is small, warty, or superficial, and ulceration is slight or absent, and in cases where the primary growth has been removed and the gland operation alone remains to do, I have nothing to urge against the method. Where, however, the growth is large or deeply ulcerated I believe there are grave disadvantages in it being disturbed in any way before it has been completely exposed for removal. I do not believe the direct laryngoscope can be passed without considerable risk of very gross disturbances. It seems to me that the growth must be liable to be squeezed, bruised, or even torn, and that septic material may be expressed from the ulcer and conveyed by the instrument to the upper opening of the larynx, whence by a few spasmodic inspirations upon the introduction of the tube it may well be carried into the lungs.

In this special class of case, therefore, I believe temporary laryngotomy to be the sounder method, since it suspends aspiration from the mouth without any interference with the growth. For these reasons I am not able to quote from my own experience with regard to the use of the intratracheal method in cases of this class. It happens, however, that in the same number of THE LANCET as that in which Dr. Shipway's letter appears there is an interesting article by Mr. Rupert Llewellyn Jones giving in detail his experiences of 49 cases of various kinds in which Meltzer's method was used. Two of these were cases of cancer of the tongue. One (Case 7) died from pneumonia. It is specifically stated that the catheter was passed without difficulty, so that we may assume that the amount of disturbance of the growth was not abnormal. The condition present in the mouth is described as a large and foul ulcer.

In the second case (No. 16) "intubation was tried repeatedly for 30 minutes but unsuccessfully, owing to infiltration of the base of the tongue," and laryngotomy was done. It is difficult to believe that this period of manipulation was unaccompanied by considerable disturbance of the growth, and that it failed to contribute to the fatal result which followed from heart failure 28 hours later.

These two cases contrast very markedly with the admirable results recorded in other conditions in Mr. Jones's paper, but I would wish to guard myself against being supposed to attach undue importance to their want of success as they occur early in the series. I quote them therefore chiefly as illustrations of the type of case in which I feel that preliminary laryngotomy is a safer procedure than Meltzer's method, and of the difficulties and complications I should fear if the latter were used.

I am, Sir, yours faithfully,

Harley-street, W., Nov. 9th, 1914. WILFRED TROTTER.

INTRATRACHEAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—Perhaps you will allow me again to occupy some of your limited space, for I see that Mr. Rupert Jones mentions my name in his article this week (p. 1087) in connexion with two cases anæsthetised by me at the Bristol General Hospital last year. The description of these cases comes from the pen of Mr. Jones. Case 49 was an uneventful anæsthesia well suited for demonstration purposes. Case 1 was of unusual interest, and although Mr. Hey Groves and myself had misgivings as to its suitability, I decided to take my chance and not to disappoint those medical men who had so kindly taken the trouble to be present. On referring to my notes I find that owing to cough and dyspnœa the patient had to be anæsthetised in the semi-recumbent position. As induction with chloroform proceeded (C.E. caused too much coughing) respiration became increasingly embarrassed, there was cyanosis, and a high-pitched whistling inspiration. The patient was intubated as soon as possible, and an immediate improvement in his condition resulted, but subsequent anæsthesia was difficult and not satisfactory, as the paralysed cord introduced an undesirable complication. Tracheotomy might have been a better solution, although Mr. Hey Groves said afterwards that "it was through the application of the method that the operation had been made possible." Case 7, in which pneumonia occurred, is interesting, but I should like to have fuller details before making any comment.

You raise the question, Sir, in your annotation (p. 1103) whether this method should be used for ordinary routine work. I do not think so. Undoubtedly Mr. Jones used these cases in order to learn the technique. Admittedly the catheterisation of the trachea is a difficulty in some patients, but there is much excellent advice on this subject in various articles by American writers which can be studied with profit. The only difficult cases to one familiar with the method are those in which a preliminary gland operation for cancer of the mouth has produced much scar tissue. So many cases of cancer of the mouth, however, are edentulous, either partially or completely, that they should not present any difficulty.

I am glad to see your remarks, Sir (in reference to the paper by Mr. W. Dakin Mart), on the principles of intratracheal insufflation. The difference between this and intratracheal administration without positive pressure cannot be too strongly emphasised. Meltzer and Auer's method has definite cardinal principles. A careful study of the literature, especially of their original articles, is essential for success, and obligatory upon all who use the method. Otherwise a very valuable discovery and a fine piece of scientific work will be brought into discredit. Chloroform and C.E. have been tried in a few cases at Guy's, but I am not justified in saying anything definite about them at present, except that chloroform appears to be unsafe, for the reason I think that the stimulating effect of inspiration upon the circulation is practically abolished. I am, Sir, yours faithfully,

Francis E. Shipway.

Queen Anne-street, W., Nov. 7th, 1914.

Obituary.

JOHN HARTLEY, F.R.C.S. Eng.,

HONORARY SURGEON TO THE DARLINGTON HOSPITAL.

The death of Mr. John Hartley, at his residence at Darlington on Oct. 3rd, will be deeply regretted by many old Middlesex men, by whom he was well known and much respected. He was the second son of the Rev. Charles Hartley, rector of Stocking Pelham, Herts, where he was born in 1857. He was educated at King's College, London, and at the Middlesex Hospital, where, after qualifying, he held the appointments of house surgeon, house physician, and resident obstetrical assistant. He then joined his brother, the late Mr. Charles Hartley, in practice at Dunmow, Essex.

Being keen on hospital work he returned to London and became clinical assistant at the Royal Westminster Ophthalmic Hospital. From there he was appointed senior demonstrator of anatomy at the Middlesex Hospital, which post he held for five years. On his resignation the staff and pupils made him a handsome presentation. During the time he was demonstrator of anatomy he was beloved by the students, and those who took an interest in their work found him a willing and accomplished helper in the pursuit of knowledge. He took his Fellowship in 1892, and four years later bought the practice of Dr. E. W. Forster in Darlington. About two years after he was appointed one of the honorary surgeons to the Darlington Hospital, which post he held till his death. For many years he spent about two hours each morning at the hospital, going carefully and skilfully into the details of every patient's illness. He always welcomed the help of his colleagues, and was ever ready to help them with advice or assistance in operations, and his opinion was much valued by a large circle of practitioners both in the town and surrounding district. The last years of his life were very busy in consultation and in surgical work. His geniality, straightforwardness, and generosity endeared him to a large circle, and his funeral was attended by a very large gathering of mourners. He leaves a widow but no family.

JAMES GREGORY MUMFORD, A.B., M.D. Harv.,

PHYSICIAN-IN-CHIEF, CLIFTON SPRING SANATORIUM AND HOSPITAL, NEW YORK.

Dr. James Gregory Mumford, who died on Oct. 18th at Clifton Springs, New York, where he was physician-in-chief to the sanatorium and hospital, was known in this country mainly through his writings, many of which have been reviewed in our columns. His "Narrative of Medicine in America" (1903) was a fascinating book, just and honest, and, as we stated in reviewing it,[1] a solid contribution towards the history of the profession in the New World. He also wrote the article on the history of surgery in Keen's "System of Surgery." Another pleasing little work was "A Doctor's Table Talk" (1912). His other works were surgical, and comprised an unconventional "Practice of Surgery" (1910), the "Surgical Aspects of Digestive Disorders" (1905), and "Surgical Memoirs and Other Essays" (1908).

Dr. Mumford was born at Rochester, New York, on Dec. 2nd, 1863. He graduated as A.B. at Harvard in 1885 and M.D. in 1890. After holding surgical appointments at the Carney Hospital, Boston, he became out-patient surgeon, and subsequently visiting surgeon, to the Massachusetts General Hospital, and assistant and subsequently instructor in surgery at Harvard Medical School. In 1912 he was appointed physician-in-chief to the Clifton Spring Sanatorium and Hospital.

THE NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.

The inaugural meeting of the National Council for Combating Venereal Diseases was held at the house of the Royal Society of Medicine on Wednesday afternoon last, when Sir Thomas Barlow presided, and explained in a brief address the aims and objects of the movement. The movement had its origin, he said, in a request from Major Leonard Darwin, the President of the Eugenics Education Society, to Sir Rickman Godlee, as President of the Royal College of Surgeons of England, and himself, as President of the Royal College of Physicians of London, to support a movement for national education on the subject of venereal diseases. Sir Henry Morris, President of the Royal Society of Medicine, having promised the coöperation of that body, a strong committee was formed to report on the incidence and prevalence of these diseases, on the provision existing for their treatment, and on the amount of instruction usually offered to the medical profession on the matter. The committee, whose work has been submitted to the Royal Commission on Venereal Diseases, went further and examined the need for popular information. They found the prevalence great, the provision for treatment, especially in London, poor, and the instruction given inadequate. It was to remedy these matters that the National Council would primarily work. But the breaking out of war offered them a special field in the aggregation of large bodies of young men in camps, with all the dangers implied to both sexes in the altered relations of the civil population. Sir Thomas Barlow was glad to announce that such work as the National Council proposed to do was heartily welcomed by Lord Kitchener, who it is known has already approved of a scheme for educating the army on such matters by qualified lecturers. The National Council will also supply a panel of such teachers and lecturers, carefully selected, and to be used in assistance of the work now going on. He closed with a few words of thanks for the coöperation which the movement was receiving from women. He proposed the following list of resolutions:—

---

[1] The Lancet, Jan. 30th, 1904, p. 307.

That it is desirable that a National Council for Combating Venereal Diseases be formed with the following aims and objects:—

1. To provide accurate and enlightened information as to the prevalence of these diseases, and as to the necessity for early treatment.

2. To promote the provision of greater facilities for their treatment.

3. To increase the opportunities of medical students and practitioners for the study of these diseases.

4. To encourage and assist the dissemination of a sound knowledge of the physiological laws of life in order to raise the standard both of health and conduct.

5. To coöperate with existing associations, to seek their approval and support, and to give advice when desired.

6. To arrange, in connexion with such organisations, for courses of lectures, and to supervise the preparation of suitable literature.

7. To promote such legislative, social, and administrative reforms as are relevant to the foregoing aims and objects.

Lord KINNAIRD, President of the Young Men's Christian Association, spoke in support of the objects of the meeting, which he said had long been before the minds of many of those interested in rescue work, but they had spoken hitherto to an uninterested public.

Sir FRANCIS CHAMPNEYS, in seconding the resolutions, said that the former attitude of recklessness towards the evils of venereal diseases had disappeared; people no longer thought that the evils must go on because they had existed for so long, nor that the sufferers were rightly punished for their sins. The fact that early syphilis was susceptible of cure had counted in the altered view, while he considered that this time of war was well fitted for the inauguration of the National Council.

Colonel H. EVERITT, representing the White Cross League, having briefly addressed the meeting on the work of his association, the seven resolutions were adopted unanimously.

Major LEONARD DARWIN then proposed that the following be the constitution of the council:—

1. The National Council for Combating Venereal Diseases shall consist of a council, an advisory board, and an executive committee.

2. The council shall consist of those persons whose names are set forth in the schedule attached, and of such other persons as may from time to time be invited to join either as individuals or as representatives of the principal societies and institutions engaged in social and educational work.

3. The council is formed for the promotion of the above-mentioned aims and objects. It shall meet at least once a year, shall receive reports from the advisory board and the executive committee, and shall determine all questions of policy and administration. Fourteen days' notice shall be given by a member of any resolution he intends to move at a meeting.

4. The advisory board shall consist of not more than ten persons to be selected by the council at its annual meeting. The advisory board shall have power to add to its number, provided that the total number of the board does not exceed 18.

5. The advisory board shall advise the council with regard to the policy to be pursued. No decision on any matter concerning questions of policy shall be taken by the council unless the advisory board shall have had an opportunity of expressing an opinion thereon.

6. The executive committee shall consist of three members of the advisory board, selected by that body and of not more than nine other persons selected by the National Council at its annual meeting.

7. The executive committee shall carry out the policy determined by the National Council, shall report to the National Council, and shall consult the advisory board on questions of policy. It shall call a meeting of the National Council at least once a year, and also at any time when so requested by the advisory board. It shall call meetings at other times for special purposes on the request of 20 members. It shall send to the advisory board, ten days before any meeting of the National Council, copies of any documents intended to be submitted to the council for consideration. It shall appoint committees, who may be given power to add to their numbers. It shall frame rules of procedure for the meetings of the National Council and of its committees.

8. The executive committee shall, as far as possible, promote the formation of local committees in important centres of population, and render them all assistance in its power.

Major Darwin explained the simplicity of the proposed constitution as being deliberate, so that the Council could either stop when its work was taken up by some other body, or develop into any greater form that might be necessary.

Dr. CHARLES J. MACALISTER seconded the motion and spoke, in reply to direct invitation, of the work that had already been done in Liverpool, on the initiative of the Liverpool Medical Institution and with the coöperation of an enlightened Lord Mayor and Lady Mayoress. At Liverpool lectures are delivered, he said, by selected men to male audiences and selected women to female audiences, and though on account of the war the lectures to males had now ceased, the audience being dispersed through the country, those to females went on.

Cardinal BOURNE, Archbishop of Westminster, spoke eloquently as to the value of the work which the National Council proposed to undertake, and Dr. INGE, the Dean of St. Paul's, poured scorn on the doctrine, which he termed blasphemous, that venereal diseases should be regarded as a divine punishment for sin.

The constitution of the Council having been adopted, Mr. CHARTERS SYMONDS proposed a long list of persons well known in medical, philanthropic, scientific, and educational circles who should form the first Council. He explained that it was intended that the Council should have the power to invite other persons to join their body either as individuals or as the nominees or representatives of societies and institutions engaged in medical, social, and educational work.

The motion was seconded by Mrs. CREIGHTON and duly carried.

Sir RICKMAN GODLEE proposed that owing to the present state of affairs due to the war the advisory board be not at present constituted, but a provisional executive committee be formed to carry on the work of the Council, with power to add to their number. It was further proposed that the Provisional Executive Committee of the National Council should be constituted as follows:—Sir Clifford Allbutt, Sir Thomas Barlow, Sir Francis Champneys, Sir Watson Cheyne, Mr. W. A. Coote, Major Leonard Darwin, Colonel T. W. Gibbard, Sir Rickman Godlee, Mrs. James Gow, the Right Hon. Lord George Hamilton, Lady Laura Ridding, the Lord Bishop of Southwark, Mr. Charters Symonds, Dr. Frederick Taylor, Mrs. Torrey, Dr. Helen Wilson; and that the honorary secretaries of the National Council should be Dr. Douglas White and Mrs. Gotto.

This motion was adopted, after which Sir MALCOLM MORRIS spoke briefly as to the value set upon the work which the National Council proposed to do by the Royal Commission on Venereal Diseases. He said that the work of that Commission had necessarily been arrested by the war, but he thought that he might mention that an interim report would be forthcoming which would be useful in the present juncture.

The proceedings closed with a few words of thanks from Sir THOMAS BARLOW to many busy persons, some from distant provincial centres, who had attended a large and representative meeting.

THE WAR.

THE CASUALTY LIST.

THE following casualties among officers in the Royal Army Medical Corps serving with the Expeditionary Force have been reported since our last issue:—

Killed: Captain Richard George Kinkead.

Wounded: Captain H. G. Gibson, Lieutenant G. R. Grant, Lieutenant C. W. B. Littlejohn, Lieutenant F. G. Thatcher, and Lieutenant T. A. O'Driscoll.

Missing: Captain A. M. Pollard.

Captain B. Johnson, previously reported missing, is now reported a prisoner of war. A letter has been received from Crefeld from Captain W. Egan, who was taken prisoner on August 28th. Captain A. D. Fraser, reported missing three weeks ago, should read Captain A. E. G. Fraser.

Lieutenant Douglas Wardleworth, R.A.M.C., has been accidentally drowned while on military duty at Havre.

Among the executive officers who lost their lives with the Royal Naval Division in the operations around Antwerp was Sub-Lieutenant Edwyn Manners Ridge, R.N.V.R., who was a Fellow of the Royal College of Surgeons of England and practised at Enfield.

HEALTH OF THE TROOPS IN THE FIELD.

As far as we are able to judge from the limited information to hand, the health of our troops in the field is satisfactory. This is very encouraging. The time of year is not favourable to epidemic disease. With the onset of colder weather and especially a prevalence of rain, life in the trenches will become very trying to all who are not constitutionally sound, and bowel complaints may be expected to prevail, dysentery, and diarrhœa due to chill. The Queen's opportune appeal to the women of the Empire for 300,000 body belts and 300,000 pairs of socks has met with a speedy and satisfactory response, and the distribution of these most opportune gifts should do much to ward off what has so often proved to be the scourge of armies. Dysentery and the liver affections that so often accompany it have always been a source of suffering and inefficiency to armies in the field. Insufficient and improper food, accompanied by chill, due to variations in temperature and insufficient clothing, are the usual predisposing causes, and may operate in cold and inclement weather as well as during excessive heat. From all we hear, the feeding of the troops has been excellent. The commissariat department has been well organised, and the supplies have been plentiful and of first-rate quality. The difficulties to contend with are enormous over such an extensive field of operations. On the other hand, the allied troops are not fighting in a hostile country, and have therefore the advantage of an abundant and regular supply of all necessary articles of food. No doubt, also, warm clothing has been, or is being, issued. In the Crimean war, when our troops were fighting alongside the French, as they are to-day, there was a marked difference in the health of the two armies during the first winter. This was due, in the opinion of all competent judges, to the much better condition of the French than of our own troops in regard to field equipment and supplies. They had shelter tents, overcoats, and excellent provision of bread and food articles generally. Our soldiers, on the other hand, were exposed to cold and wet without adequate protection, the regulation clothing was most unsuitable, and the feeding bad, consisting almost exclusively for a considerable time of salt meat and biscuit, without vegetables. Subsequently the manifest deficiencies were rectified, and the British troops during the second winter were much healthier than the French force. At the present time our supply department seems to have been extraordinarily well managed in regard to all essentials. There is, however, plenty of room for the aid that may be given by private benevolence. The belts and socks that have been promised will be most valuable, and we hope are already on the way to the field of action. Allusion was made in these columns recently[1] to the danger of importation of infectious disease in army clothing made by out-workers. A tailoress making army greatcoats was at work in a house where scarlet fever had broken out. Such a risk of introducing infection should be rendered impossible. Tetanus still appears in many cases of wounds, probably due to contact with specifically contaminated earth. It is difficult to see how this can be avoided under the conditions that prevail. The use of the specific serum, in addition to the ordinary antiseptic measures, may be expected to control this danger. Our troops, from all we can gather, are admirably fed and clothed, and their spirit, as we know, is magnificent. What is needed now is to preserve their health and sustain their spirit. We feel sure that no effort will be wanting on the part of the nation to secure this end. We are told that the Germans have pianos in their trenches and that they sing a great deal. Our troops may not have the instrumental accompaniment, but are probably quite as well able to sing as those on the other side. Meantime let there be more and more belts and socks got ready in good time to replace those that become unserviceable.

INDIAN SOLDIERS' FUND.

As we have already recorded, a very strong representative committee, under the chairmanship of Sir John Hewett, G.C.S.I., C.I.E., has been appointed to administer the results of the appeal for the Indian Soldiers' Fund—a fund to supplement the provision for ambulances, base hospitals, and the necessaries of war for the Indian Force of some 40,000 or 50,000 men despatched in such dramatic circumstances to fight in France with the Allied troops. The Order of St. John of Jerusalem, whose influence and work in India is described this week elsewhere by one of our correspondents, has provided a hospital, and the Indian Fund also desires to supplement the clothing and comforts already provided for the Indian troops by the Government with articles which it does not fall within the responsibility of the Government to offer, and to repair the almost inconceivable wastage of war. The Indian Fund was started by grants from the Order of St. John of Jerusalem (£10,000) and the Viceroy's Imperial War Fund (£6666), and soon reached a total of £55,000. It now stands at over £80,000 we are told, but a far larger sum can be spent with advantage. Donations of money may be sent to the honorary secretaries of the Indian Soldiers' Fund at 1, Carlton House-terrace, S.W.—Mr. P. D. Agnew and Mr. E. H. Blakesley. Clothes or comforts may be sent direct to the Warehouse Subcommittee at 29, Somerset-street, London, W. A list of 12 subordinate committees to the General Committee of the Indian Soldiers' Fund was rapidly formed, and Sir Havelock Charles and Sir Trevredyn Wynne went to France to be in a position to reply to any questions dealing with voluntary aid in hospitals and ambulance work of all kinds, with special reference to the work of the Indian Soldiers' Fund. They have reported that the wounded are receiving every possible care and attention in France, and that there is a large field for voluntary aid in ambulance work to supplement regular ambulance work, and working under the directions of the regular Army Medical Service. With respect to such work as the Indian Soldiers' Fund was specially constituted to undertake, they reported, after an interview with Sir Savile Crossley, Commissioner with the Red Cross in Paris, that the Order of St. John of Jerusalem should not establish a separate organisation to work its own motor ambulances, particularly as the French authorities would not readily understand the installation of another ambulance association. They discussed the delivery of clothing and comforts to the Indian troops at the front with the Adjutant-General and Quartermaster-General at head-quarters in the field, with the Generals commanding the lines of communication and the Indian Expeditionary Forces, and with Sir Savile Crossley, and they arrived at a method in which it would be possible to deliver stores to the Indian troops at the front. Their net conclusion is that the Indian Soldiers' Fund must establish a base depôt in France at a seaport, and if necessary sub-depôts between the port and the front; that stores from these depôts must be delivered to the different Indian regiments by a motor lorry service and worked by the Indian Soldiers' Fund. The scheme, after official sanction, will entail the provision of six motor lorries and two motor cycles, three passenger motor-cars, and an officer with two assistants. Mr. Elles has volunteered to take charge, and Mr. Fenton, who is the son of Mr. Du Cros's agent in Paris, will act as one of the assistants. The further staff required to work the lorries and cars will be enlisted, and a suitable house must be rented in Boulogne for a base depôt, when the stores already in hand can be sent there. The stores will then be run to the rear of the Indian contingent, the motor cyclists acting as commercial travellers to let regiments know where the supply lorries are and to ascertain what is wanted, as well as to regulate other stores being sent. Sir Alfred Gaselee has expressed his willingness to proceed to France to make the necessary arrangements, which should ensure the disappearance of all preliminary difficulties.

---

[1] THE LANCET, Oct. 24th, p. 1003.

AGAINST LOSS OF MEN BY SINKING OF SHIPS.

The most serious risk before our fighting ships in this war is destruction by submarine mines or by torpedoes. Under these circumstances many men are struggling in the water, and the more wisely preparations are made for these emergencies the more lives will be saved. It will be well, then, that we reproduce from THE LANCET of Oct. 7th, 1911, the measures the Japanese found most helpful in these difficult situations, as reported in the fourth volume of the official Japanese history of the war with Russia in 1904–05, and translated by Staff-Surgeon Chemin, of the French Navy, for the *Archives de Médecine et Pharmacie Navales* for September, 1911. Rule 1 is that the men should not on any account remove their clothing, even heavy clothing, before jumping overboard; the air entangled in it is only gradually displaced by water, and meanwhile it buoys the man up a little and goes on acting as a non-conductor of heat, and so for a time lessens chill and minimises shock. We know of an officer who was thrown overboard from a torpedo-boat in the Mediterranean in great-coat and sea-boots. When in the water he managed to get off one sea-boot, but finding himself pretty comfortable, he did not let it go or attempt to remove the other, and was very shortly picked up with his clothing intact. So clothing, however heavy, does not sink a man for a time. The chief danger from clothing comes later, when in now thoroughly soaked clothing the wearer is being rescued. He is by this time exhausted and cannot do much, or perhaps anything, to help himself and as he is being lifted out of the water into the boat he gets rapidly heavier and heavier, and this increased weight may overpower the too light grip of him taken by his rescuers, who had not expected this so rapid increase of weight. A man in the water should not try to swim except for some definite purpose, but be content to float and be satisfied if he can just keep his mouth above water, and he will be greatly assisted by the air-collars so thoughtfully provided by the Admiralty. The best life buoy, short of a cork jacket, is a lashed-up hammock; it does not turn over and over like a cask, and there is always the lashing to hang on to; and a hammock has been known to keep a man afloat for 24 hours. A man, especially if exhausted, should never let go of his hammock, however near the boat is, until his rescuers have a good hold of him. Many a man is lost through neglect of this little precaution. The boats rescuing men should be as low-sided as possible. It is a great trouble to get men into launches with high sides, and took a long time. The quicker each man can be picked up the more men obviously will be saved. When a man has been rescued get his wet clothes off, wrap him in dry blankets (have some in the boats), give him a hot drink (not an alcoholic drink), and lay him down in a warm part of the ship (flats or ammunition passage), and then will have been done for him the best thing possible. These instructions may be summed up thus:—"Don't take your clothes off; don't try to swim; don't let go of your hammock."

ENTERIC FEVER IN WAR.

Sir William Osler will open a discussion at the next meeting of the Society of Tropical Medicine and Hygiene on Friday, Nov. 20th, at 8.30 P.M., at 11, Chandos-street, Cavendish-square, on "Enteric in War with Means for its Prevention." In view of the exceptional interest of this subject it has been decided to invite members of the medical profession who are not Fellows of the Society to attend as visitors, and especially any who may have had recent experience of the inoculation of the troops. Any who will send their names to the secretaries of the society, 11, Chandos-street, Cavendish-square, W., will be furnished on request with a précis of Sir William Osler's paper introducing the subject.

THE QUESTION OF EXPLOSIVE BULLETS.

The photographs and radiograph which we reproduce below were brought to us by a Belgian doctor as a clear and irrefutable proof that the injured soldier was struck by an explosive bullet. It is common knowledge that the vast majority of wounds which earlier in the war were attributed to explosive bullets on account of the enormous destruction of tissue are capable of more decent explanation. The point was well summed up last week by one of our correspondents in describing the wounds which he had been treating in a hospital at Chambéry, where all the appearances that might be attributed to explosive bullets were obtained both from shrapnel and from modern conical high-speed bullets which have either twisted on their axis of direction towards the end of their course or which have undergone *ricochet*. But that some revolver ammunition of an explosive type has been employed seems probable. Our correspondent considered that a study of the photographs would convince the most sceptical that in this case an explosive bullet had been employed.

CONSULTANTS TO THE ROYAL NAVY.

The following names of temporary consultant physicians and surgeons appear in the current issue of the Navy List:—Sir W. Watson Cheyne, Mr. G. R. Turner, Mr. Arthur Edmunds, and Mr. C. H. M. Hughes (Naval Hospital, Chatham); Mr. G. Lenthal Cheatle, Dr. H. D. Rolleston, and Mr. C. W. Morris (Naval Hospital, Haslar); Mr. Raymond Johnson (Naval Hospital, Plymouth); Sir Alfred Fripp and Dr. D. A. Shields (H.M. Hospital Ship *Sheelah*); and Sir William Macewen.

SURGEONS IN THE "GOOD HOPE" AND "MONMOUTH."

In the naval action off the coast of Chile it is feared that both H.M.S. *Good Hope* (Admiral Cradock's flagship) and H.M.S. *Monmouth* have been lost with their brave crews. According to the Navy List for November the surgeons serving on board these two cruisers were as follows:—*Good Hope*, Fleet-Surgeon James J. Walsh, Surgeon Francis C. Searle, and Surgeon (Reserve) Fernand L. T. M. de Verteuil. *Monmouth*, Staff-Surgeon Henry Woods and Surgeon Albert J. Tonkinson. We earnestly hope that later messages may bring news of survivors.

THE WRECK OF THE "ROHILLA."

The hospital ship *Rohilla*, which, as reported last week, was wrecked off the Yorkshire coast on Oct. 30th, carried the following medical men on board, all of whom, we are glad to state, have been saved, although the ship is a total wreck: Fleet-Surgeon Ernest C. Lomas; Surgeon S. L. McBean; Temporary Surgeon T. H. Cresswell; Surgeons R.N.V.R., T. C. Litler Jones, H. Leith Murray, A. E. W. Hird, and L. S. Ashcroft. Mr. F. W. Paul, who was on board as civilian dental surgeon, was also saved, as were the four nursing sisters.

OUR BELGIAN REFUGEE COLLEAGUES.

Belgian medical men now residing in London, at a general assembly of their number held last week, passed a resolution, which we reproduce below, showing their real recognition of anything which their English colleagues may have been able to do for them in their sad position. The resolution runs as follows:—

Aux Autorités Médicales Anglaises.

Les médecins Belges résidants à Londres, réunis en assemblée générale le 2 Novembre, 1914, ont l'honneur de présenter aux hautes autorités médicales Anglaises les sentiments de leur plus vive gratitude pour l'insigne honneur dont ils viennent d'être l'objet de la part de leurs confrères de la Grande-Bretagne. Ils n'oublieront pas que dans ces moments de détresse et de deuil pour la pauvre Belgique si éprouvée, la noble Angleterre est venue au secours de leurs compatriotes dans un élan de générosité admirable dont ils lui sont profondément reconnaissants. Ils peuvent affirmer que de leur coté ils n'useront qu'avec la plus extrême délicatesse de la grande faveur qui leur a été accordée et prient leur chers confrères de vouloir bien agréer l'expression de leurs sentiments de gratitude et de chaleureuse confraternité.

The resolution is signed in behalf of the Belgian refugee doctors by Dr. Clément Philippe.

BELGIAN MEDICAL MEN AND PHARMACISTS.

The committee appointed to consider the position of Belgian doctors and pharmacists in Belgium has proceeded to work strenuously. All communications should be addressed to Dr. Sprigge, 423, Strand, London, W.C.

OBITUARY OF THE WAR.

RICHARD GEORGE KINKEAD, M.B. R.U.I.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain R. G. Kinkead, who was killed in action on Oct. 31st, was the only surviving son of Dr. R. J. Kinkead, professor of midwifery in University College, Galway. He received his school education in the Grammar School, Galway, and Portora Royal School, Enniskillen. He entered Queen's College, Galway, and received his professional education there and at the Richmond Hospital, Dublin. He received the medical degrees of the Royal University in 1908. After a year as assistant house surgeon in the Coventry and Warwickshire Hospital he obtained a commission in the Royal Army Medical Corps. When the war broke out he was stationed in South Africa. He was called to Europe for service, and left England for the front on Oct. 6th. He was attached to a Hussar regiment. In his last letter home, written five days before his death, he wrote with enthusiasm of the magnificent spirit of both officers and men. Kinkead was a most promising officer. With his father, one of the most respected men in the Irish profession, there is universal sympathy.

SYDNEY NELSON CROWTHER, M.R.C.S. ENG., L.R.C.P. LOND.

Mr. Sydney Nelson Crowther, senior assistant medical officer at the Surrey County Asylum, Netherne, Merstham, was killed in action whilst on service with the British Expeditionary Force as a motor-cycle despatch rider. He was the fourth son of the late Alfred Hallworth Crowther, a solicitor, and was born at Keston, Kent, in 1874. He was educated at Warwick School and at Westminster Hospital, where he acted as house physician and house surgeon. He went out to South Africa as a dresser in the Imperial British Yeomanry Field Hospital, receiving a medal with four clasps. He qualified at the English Conjoint Board in 1903. In 1906 he was appointed assistant medical officer at Brookwood, and in 1909 was appointed senior assistant medical officer at Netherne on the opening of that asylum. He was a man of exceptional capabilities, who will be much missed in the county of Surrey, especially as he had just been appointed to succeed Dr. F. C. Gayton, who was retiring from the post of superintendent. In addition to his medical capacities he was an ardent sportsman, having played at football for his county and the United Hospitals and the British Rugby team that toured round the world; he was also a good cricketer and golfer. On the outbreak of the present war he at once joined the Royal Engineers as a motor-cycle despatch rider, and was given the rank of corporal. He sailed for the front on Sept. 12th, and was killed in action on Oct. 18th. His death has cast a gloom over both Surrey asylums, where his kindly nature, generosity, and sportsmanlike qualities made him a general favourite.

CECIL TAYLOUR CONYNGHAM, M.B. DUB.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain C. T. Conyngham, who has been killed in action in East Africa, was the son of Mr. Henry Conyngham, a member of the well-known firm of chemists, Messrs. Hayes, Conyngham, and Co., of Dublin. He was educated at St. Andrew's College, Dublin, and Trinity College, Dublin. While in college he was a good all-round athlete. He was a successful sprinter; he swam for the college team; and he played in a team which won the Leicester Cup for the Wanderers' Football Club in 1906. He received his degrees in medicine and surgery in 1906, and soon obtained a commission in the Royal Army Medical Corps. When war broke out he was stationed in India, and he only left Bombay for East Africa on Oct. 16th.

THE BRITISH RED CROSS SOCIETY.—The summary of the work for the week ending Nov. 10th states that 359 hospitals have been accepted by the War Office, containing 11,730 beds, including 1495 beds accepted during the past week, and distributed among the army commands as follows: London 745, Southern 3487, Aldershot 633, Eastern 3437, Northern 1803, Western 1436, and Irish 189. A number of Red Cross Voluntary Aid Detachments are being utilised in connexion with these hospitals.

At the Netley Red Cross Hospital nine huts are occupied by sick and wounded, which includes 60 Indians. The pack store, steward's store, and dispensary are almost complete, thereby releasing the huts which have been used for these purposes. 300 beds are expected to be ready by the end of the week. Medical officers and nurses are going to their regular quarters, thus giving more huts for patients. The night orderlies' dormitory, bath-rooms, and extra stores have been completed and occupied. The large dining hall for patients will be finished in ten days. The patients in the hospital express themselves as comfortable and well satisfied. Sir Frederick Treves and Sir Benjamin Franklin visited and inspected the hospital. Two members of the Indian council have also inspected the Indian ward. For ambulance purposes 84 cars have been despatched to the front; four of these are in temporary use at Southampton and another at Oxford,

The following personnel has been despatched on the dates and to the places enumerated:—Boulogne, Nov. 4th, 1 surgeon. Boulogne, Nov. 5th, 5 surgeons and 5 dressers. Paris, Nov. 6th, 1 splint-maker. Boulogne, Nov. 9th, 11 dressers. Sir Henry Norman's Hospital, Nov. 10th, 1 doctor. Nov. 9th, 20 nurses despatched to France for Lady Norman's Hospital; 26 nurses sent to home hospitals.

The following stores have been despatched during the last week: 1939 cases to France and 1231 to various parts of England to 102 hospitals in all. Demands from Boulogne and Calais increase, but requisitions from Rouen are not so great owing to the good reserve stock. Applications for stores are now of a very varied nature, including foods of all kinds and medical requisites of every sort, resulting in the purchase of a large percentage of the supplies, which permits of drawing to a very small extent on stock. The necessity of the public subscribing money in lieu of goods is accentuated by recent requisitions.

Sir Frederick Treves states that owing to the generosity of Mr. Fielden the society has been able to acquire for an almost nominal sum the well-known steam yacht *Paulina*. The ship is 380 tons, draws $11\frac{1}{2}$ feet, and is capable of a speed of $11\frac{1}{2}$ knots. She has an admirable crew of 19 men. She is at this moment undergoing the process of being fitted for a hospital ship, and when complete will have 21 beds for private soldiers and three separate cabins for officers. She will carry a doctor and two orderlies.

The running expenses of the yacht are estimated at between £300 and £400 per month. It is the pleasure of Her Majesty Queen Alexandra that the yacht should be named *Queen Alexandra*. The yacht has received the necessary Admiralty warrant as a hospital ship, and will be ready to commence her work in about three weeks' time. She is lying at present at Itchen, Southampton.

FRENCH RED CROSS SOCIETY: THE NEED FOR MOTOR AMBULANCES.—We have received a communication, signed by the Duke of Portland (honorary president), Sir Francis Bertie, M. Paul Cambon, Lord Charles Beresford (chairman), and other members of the British Ambulance Committee, appealing for motor-cars for the French Red Cross Society. The Queen, Queen Alexandra, and the Prince of Wales have sent messages of encouragement to the committee, while the French Government through the French Ambassador in London has expressed hearty approval of the scheme. Moreover, the French Red Cross Society states that in many directions the ambulance transport of the French army has almost broken down. Cars should be lent to the French Red Cross Society through the committee for a minimum period of three months. A minimum expenditure of £50 upon each car supplied is necessary to convert it into an ambulance and complete its outfit, and the cost of maintenance is estimated at about £10 a week, so that those who may have no cars of their own to lend are requested to send subscriptions towards the first sum of £50,000 with which the committee propose to begin to carry out their purpose. Those who are willing to lend cars should communicate with the joint honorary secretary, Mr. B. Pegman, Queen's Mansions, Westminster, S.W. According to the statement of the committee France has already used up nearly all the motor-cars available for ambulance work, and the wounded of our gallant ally are suffering terribly owing to the consequent delay in transport from the front to the nearest available hospital. Now that the English people have done what was urgently necessary in this matter for our own army the committee hopes that its appeal for motor-cars and for funds for their upkeep will meet with an instant and generous response.

THE INDIAN ST. JOHN AMBULANCE ASSOCIATION AND THE EUROPEAN WAR.—One of our Indian correspondents writes as follows:—The St. John Ambulance Association is the only Red Cross Society in India, and has taken up with the greatest promptitude its duties in the present European crisis. The society has during the past five years built up a position as a national institution in India, and has established in this brief period no less than 300 centres in every corner of the great Indian Empire. The value of this well-thought-out organisation became at once apparent on the outbreak of the present war. Forty-eight hours after the news reached India a circular letter was issued to all centres of the association pointing out that England was now at war and that there was evidence of intense enthusiasm on the part of the public and a great desire to help our troops in the field. One of the most important functions of a Red Cross or ambulance society is to direct such patriotic enthusiasm into correct channels, and the letter suggested that centres of the association should form ladies' committees with the following objects—viz. (1) to collect funds; (2) to collect gifts of articles likely to be of use to troops on service; and (3) to collect material for ambulance detachments, should such be organised.

This letter was promptly followed by a meeting at the headquarters of the Indian Government. Addresses were made by Surgeon-General W. Babtie, Director of Medical Services in India, and Surgeon-General Sir C. Pardey Lukis, Director-General of the Indian Medical Service, outlining a scheme for the collection of gifts likely to be of use to troops on service. This was followed by the publication of a list of articles compiled by Surgeon-General Babtie in conjunction with the chief lady superintendent of the Queen Alexandra's Nursing Service. In a letter distributing these lists it was pointed out that they were mainly meant to supplement articles already provided by Government, and not to supply deficiencies. It had been found in practice very convenient that in the time of war both nurses and medical officers should have extra articles of this kind which are absolutely at their disposal without having to account for them officially. The Indian Council forthwith organised a depôt at Bombay, where all goods were received, classified, suitably packed, and handed over to the military authorities for despatch to our troops on active service. The railway authorities carry these Red Cross gifts from every part of India free of all charges.

With reference to personal service the Indian Council has under formation in every station in India Voluntary Aid Detachments, consisting of persons holding its certificates. These detachments consist of (*a*) a commandant who is, if possible, a medical practitioner; (*b*) at least two men trained in first aid; and (*c*) seven women who must hold both the first aid and nursing certificates. This personnel is recognised, registered, and inspected by the military authorities, and the Director of Medical Services in India is prepared to employ them at railway rests, camps, &c. The ladies' committees of the St. John Ambulance Association in India are only concerned with the sick and wounded, as the provision of gifts and comforts for actual combatants, however laudable, is no concern of a Red Cross Society. The response to the appeal from all parts of India has been so remarkably prompt that Surgeon-General Babtie has decided to revise the list of articles sent and has framed a list of what are now called replacement units for ten beds. These units contain all articles which it is necessary to repeat or replace. In addition to the hospitals in the theatre of war there will be hospital ships plying regularly between Bombay and Europe as well as ambulance trains in India which will require comforts on a special scale. The association, moreover, will be required probably to provide comforts for rest camps and rest stations on the railways. In addition to the ordinary units the Indian branch of the association has designed what is called the Red Cross bag, containing comforts for *invalided* British and Indian soldiers when they leave hospital. It will be gathered from the foregoing that the Red Cross services in India will not end till the war does. The association's system of providing gifts and comforts for the troops, British and Indian, has received the approval of both the Viceroy and the Commander-in-Chief, and it has also been asked to assist the military authorities in obtaining recruits for the Army Bearer Corps during the war, and has been very successful in this direction. Indeed, the services of the St. John Ambulance Association have become so valuable to the Government of India and military authorities that Major R. J. Blackham, honorary general secretary of the association, for some six years has been placed on special duty by the Commander-in-Chief to direct and control all Red Cross work in India. This is probably the highest recognition any similar society has attained.

RED CROSS ACTIVITY IN DUBLIN.—Our Dublin correspondent writes:—For some weeks past there has been in existence a County Dublin branch of the British Red Cross Society which has been working in conjunction with the St. John Ambulance Association. At a public meeting held last Monday in the theatre of the Royal Dublin Society, the Lord Mayor presiding, it was decided to form a branch for the city of Dublin. Her Excellency the Countess of Aberdeen was elected president, and various officers and committees were appointed. Collections in aid of the funds of both county and city branches are to be made in the streets of Dublin on Nov. 14th. Lady Aberdeen has sketched a new scheme of activity for Red Cross workers in Dublin. She suggests the establishment of a hospital which might be furnished by those interested in Red Cross work, and which would give an opportunity of extending the training of women holding first-aid and nursing certificates. In the daily papers of Nov. 10th Sir Thomas Myles makes a somewhat similar proposal. He draws attention to the fact that the recent arrivals of wounded soldiers from France have taxed the Dublin general hospitals to their full capacity, unless serious inroads are to be made on the accommodation normally required for the civil population. He suggests the immediate erection of a wooden or iron temporary hospital in the Phœnix Park, capable of holding 1000 beds. It should be divided into blocks with not more than 200 beds in each. There are many Dublin surgeons who would willingly undertake the surgical work gratuitously, if the Government employed a reasonable number of young men as house surgeons. The control of the nursing should be in the hands of trained nurses, and under them the general nursing could be undertaken by the women who for some months past have been undergoing voluntary training in hospitals to prepare them for emergency work.—The *Oxfordshire* hospital ship arrived in Dublin last week with some 700 wounded officers and men, most of whom were accommodated in the hospitals of Dublin, military and general. The cases are, speaking generally, more serious than those received earlier. The great majority of the patients are suffering from septic wounds, more or less serious, but comparatively few show any signs of general sepsis. The infection generally appears to be of staphylococcus aureus, though a certain number of wounds have bacillus pyocyaneus present.

WOUNDED SOLDIERS AT BELFAST.—The first party of wounded soldiers allocated to Belfast arrived on the evening of Nov. 5th. The Bibby liner *Oxfordshire* brought 700 British wounded from Boulogne to Dublin on the morning of Nov. 5th, and about 150 of these were sent northward by means of the new finely-equipped ambulance train, which was specially built—since the war began—by the Great Northern Railway Company of Ireland. About 20 of the less serious cases were taken *viâ* Portadown to Omagh; the remainder came on to Belfast, where 65 of them found accommodation in the Royal Victoria Hospital; 20 were taken to the military hospital at Victoria Barracks; while the balance were sent by motor car to Downpatrick. The most ample preparations were made at the Great Northern terminus, Belfast, for the reception and transference of the patients to the hospital. A large number of private motor cars were placed at the service of the Royal Army Medical Corps, in addition to motor ambulances of the corporation, the Red Cross Society, and the Ulster Volunteer Force, and the patients were rapidly and easily removed to the hospitals. A number of ladies provided hot soup and cigarettes, &c., for the wounded while at the Belfast station, which were greatly enjoyed. The majority of the soldiers wounded got their injuries recently in the Ypres district. At the Royal Victoria Hospital the men say their injuries were, as a rule, caused by shrapnel or rifle bullets. They speak highly of the artillery of the Germans, but think little of the enemy as a fighting individual. One man has lost an eye, another has a serious injury to the hip-joint, another has a bad smash of one shoulder-joint, another has been shot through the cheek, others in the knee, foot, and arm. All are cheerful, most modest in their description of their experiences, and very grateful for any attention. Numerous X ray photographs indicate the lesions and the presence of the shrapnel.

MEDICO-MILITARY NOTES FROM AMERICA.—In the October issue of the *Military Surgeon*, published in Chicago, Captain W. H. Crum, Medical Corps, U.S. Army, discusses the physique of the Medical Corps orderly, the stretcher bearer, or as he, following continental practice, names him, "the sanitary soldier." The physical toil of carrying men off the field on stretchers is very exacting. Captain Crum points out that the bigger and stronger the stretcher bearers the more quickly will the work be done. He set two squads each to carry a man of $11\frac{1}{2}$ st. on a stretcher twice round a half-mile racecourse. One squad averaged 5 ft. 10 in. and $13\frac{1}{2}$ st.; the other pair 5 ft. $7\frac{1}{4}$ in. and 10 st. 5 lb. The shorter pair did the first circle in $12\frac{1}{2}$, the second in $14\frac{1}{2}$ minutes and changed ends nine times; the bigger men did the first circle in 9, the second in 12 minutes and exchanged places five times. The big men did a quarter more work in the same time. Therefore Captain Crum desires to see big, powerful men enlisted in the sanitary corps, men, he says, "as good as those of the Mountain Artillery," evidently a corps d'élite in the United States. Still, that army which has in the firing line all its most powerful soldiers will probably secure that its enemy has the most wounded, and that its own less powerful orderlies have less call made upon their services. Major A. E. Truby, Medical Corps, U.S. Army, tells how to provide hot water easily and in plenty in camp. Alongside the destructor, whose fire is always alight, there is a water barrel, from the bottom whereof a three-quarter inch pipe leads to the destructor, takes a complete turn round within the fire, and leads back to the barrel some 8 inches above the bottom. This is an adaptation of the ordinary method of household hot water heating used in Canada and the United States. The description is clear and well illustrated, the apparatus, given the barrel and the destructor, quite easy to instal. Lieutenant DeLanney, describing the giving of ipecacuanha for dysentery, first secures his patients against the distressing nausea by putting 15 grains of the powder into gelatine capsules which he has soaked for some hours in 20 per cent. formaldehyde solution and has afterwards dried. Major Reno, who devotes much attention to the improvement of the military efficiency of the Medical Corps, recommends a sort of metal thimble to fit over the head of tent pegs to prevent their splitting when being driven. It could not be but very useful if always at hand. The Schäfer method of artificial respiration[1] has been officially adopted in the United States Army. There is translated the discussion of agglutination phenomena in 144 cases of paratyphoid B infection in Japanese sailors and soldiers already immunised, all of them, against typhoid fever. In most cases the paratyphoid B agglutination was in a weaker dilution than the Widal. Sometimes, however, they occurred only in similar dilutions, and at times this position was reversed. Numerous abstracts of papers are presented from all the medical military journals of the world. On the whole, they suggest that the work of the medical officer at the front is chiefly sanitary and preventive, and that anything beyond first aid to the wounded must be done by surgeons on the line of communications, and that, if possible, serious operations should be undertaken only in the base hospitals.

WOUNDED SOLDIERS IN SCOTTISH HOSPITALS.—Another hospital train arrived in Edinburgh on Nov. 5th. The men were sent to the different hospitals—Craigleith, the Royal Infirmary, and Dalmeny. The men had come straight from the firing line, and among those who were sent to Dalmeny were two of the London Scottish who had been in the first great charge made by Territorials. From the nature of the wounds, as these are compared with those of the first contingent, the close and bloody nature of the recent struggles at the front may be realised. Among the first contingent practically all the wounds had been caused by shrapnel. So far as the contingent which arrived on the 5th were concerned, shrapnel wounds were few, and there is eloquent testimony to recent infantry struggles in the fact that practically 90 per cent. of the wounds are due to rifle bullets.

MANCHESTER IN WAR TIME.—Our own correspondent writes as follows concerning university and medical matters: "Naturally, the outbreak of war has had an effect on the attendance at the University. On the whole there is a diminution of about 25 per cent. so far as entries are concerned. As to the medical school itself, the following is approximately correct. As compared with the corresponding period last year there are between 60 and 70 fewer students on the register of the medical school. The number of new entries in medicine for the degree and other qualifications shows an increase over last year's figures. There is a diminished entry for dental qualifications, as well as for the diploma of Public Health and that of Veterinary State Medicine. The University has offered hospitality to two medical students from the University of Ghent. These students are pursuing their studies in the medical school. The professorial staff is doing its best to arrange for the reception of professors and their relatives who have been obliged to leave Belgian universities. It is stated that Professor Boycott will in due time proceed to take up an appointment in London, so that by and by there will again be a change in the pathological department of the University. Over 4000 wounded—English, Belgian, and a few German soldiers—have been received at the Manchester or Western Base Hospital. Over 1100 have been dealt with in the Manchester, Salford, and adjoining hospitals; some have been sent to hospitals in neighbouring towns. The Lancashire towns—in spite of great depression in the cotton trade—are making and have made strenuous endeavours to accommodate both the wounded and the numerous Belgian refugees who have reached Manchester. On Nov. 10th there was a public funeral of seven brave Belgians who had died in the local hospitals as the results of injuries received in the battles in Flanders."

---

[1] THE LANCET, March 27th, 1909, p. 895.

PROHIBITED EXPORTS.—In a Prohibition Order issued as a supplement to the *London Gazette* of Tuesday, Nov. 10th, there is included, besides military articles and the raw materials out of which explosives can be made, a long list of drugs. Notable amongst those which are forbidden to be exported to all destinations are acetanilide, acetylsalicylic acid, aconite, antipyrin, antimony, chloral, carbolic acid, collodion, veronal, formic aldehyde, hydrobromic acid, emetine hydrochloride, ergot, opium, phenacetin, potash salts, sulphonal, and tartaric acid. Chloroform and ether are not included, but methyl alcohol and spirits are. Amongst the drugs forbidden to be exported to all foreign ports except those of France, Russia, Belgium, Spain, and Portugal are bismuth salts, camphor, castor oil, iodine, mercury salts, picric acid, sulphur, and sulphuric acid. The Prohibition Order applying to all destinations abroad other than His Majesty's dominions includes certain provisions and victuals—e.g., living animals (for food purposes), barley, oats, butter, cheese, eggs, margarine, wheat and wheat flour, and woollen goods and clothing. Sugar is prohibited to all destinations other than the Channel Islands, Malta, Gibraltar, the Falkland Islands, St. Helena, the East Africa Protectorate, and the British West African Colonies and Protectorates.

FIRE PRECAUTIONS IN EMERGENCY HOSPITALS AND REFUGEE HOSTELS.—A free public issue is now being made by the British Fire Prevention Committee of the necessary "fire warnings" for emergency hospitals, convalescent homes, and refugee hostels. These "warnings" take the form of a small red poster measuring 8 in. by 20 in., embodying useful reminders and hints as to matches, smoking, illuminants, open fires, stoves, and the use of spirit, celluloid, and similar dangerous substances. Copies are supplied upon written application to the Registrar of the Committee, 8, Waterloo-place, Pall Mall, S.W., stating the number of beds or number of refugees which the applicant has to deal with. Summarised translations in the Flemish and French languages on posters of a somewhat smaller size will also be provided on request by the British Fire Prevention Committee.

GERMAN TREATMENT OF TETANUS.—Professor Weintraud, of Wiesbaden, refers in the *Berliner Klinische Wochenschrift* of Oct. 19th to the increasing occurrence and heavy mortality from tetanus in war time. He advocates the following course of treatment. 1. Prophylactic serum injection for all suffering from wounds contaminated by mud or earth. 2. Careful observation of slight initial symptoms and "localised" tetanus. 3. Open antiseptic treatment of wounds. 4. Injection of 100 units of antitetanic serum once or twice on the outbreak of symptoms. 5. Consecutive use of a 15 per cent. solution of sulphate of magnesia in doses of 5 to 10 grammes to be injected into the spinal canal, after a corresponding amount of fluid has been let out. The treatment must be conducted in hospital wards and supervised carefully by several physicians. Three cases thus treated in Wiesbaden all recovered.

THE London School of Tropical Medicine will be pleased to offer the hospitality of the school to any Belgian medical graduate who may desire board and residence while prevented from returning to his own country. The committee will also be pleased for any graduate residing with them to attend the classes of the school.

WOUNDED IN UNIVERSITY COLLEGE HOSPITAL, LONDON.—University College Hospital, as a section of Queen Alexandra's Military Hospital, provides 100 beds for sick and wounded soldiers. All these beds are now fully occupied by patients drafted during the past two weeks from the base hospitals in France. A large number of regiments are represented, and there are in addition about 20 Belgians.

BRITISH AMBULANCE FOR SERBIA.—At the close of last week, according to the Malta correspondent of the *Morning Post*, a British transport reached that island from England, having on board a British ambulance party for Serbia, consisting of 31 medical men and 27 nurses, with 12 orderlies, under Professor J. T. J. Morrison, senior surgeon to the Queen's Hospital, Birmingham. The party has been organised by the Serbian Relief Fund in London with the assistance of the Order of St. John of Jerusalem.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Dr. H. K. Anderson, F.R.S., Master of Gonville and Caius College, has been re-elected to the Council of the Senate of the University for the ensuing two years.—The special Board for Medicine has presented a report on the relation of Addenbrooke's Hospital, and the teaching of clinical medicine and surgery, to the proposed grant from the Board of Education to the medical school of the University.—Mr. Colin Mackenzie, Emmanuel College, has been approved for the degree of Doctor of Medicine *in absentia*.—Mr. John Richardson Marrack, M.B., B.C., has been elected to a Fellowship at St. John's College.

UNIVERSITY OF EDINBURGH.—The following scholarships and bursaries in the Faculty of Medicine of Edinburgh University have been awarded: Crichton research scholarship in anatomy to Stuart Bolton, M.B., Ch.B.; Vans Dunlop scholarship in anatomy to Robert Walker; Vans Dunlop scholarship in physiology to Robert Mailer; Houldsworth scholarship in pharmacology to Benjamin J. Ryrie; Grierson bursary in anatomy and physiology to Andrew O. Ross; Grierson bursary in pathology to Andrew J. Caird, M.A.; Crichton bursary in preliminary subjects to James McNabb, M.A., B.Ch.; and the Mackie bursaries to William B. Ross and Robert McGarrol.

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $250, will be made on July 14th, 1915, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the College, Mr. Francis R. Packard, 19, South 22nd-street, Philadelphia, on or before May 1st, 1915. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. The successful essay or a copy of it will remain in possession of the College; other essays will be returned upon application within three months after the award. The Alvarenga prize for 1914 has been awarded to Dr. H. B. Sheffield, New York City, for his essay entitled "The Fundamental Principles Involved in the Use of the Bone Graft in Surgery."

UNIVERSITY OF LONDON.—At the meeting of the Senate on Oct. 21st the Vice-Chancellor, Sir Wilmot Herringham, was granted leave of absence for as long as might be necessary during his appointment as consulting physician with H.M. Forces at the seat of war; and the Dean of the Faculty of Medicine, Sir Alfred Pearce Gould, was appointed to act for the Vice-Chancellor during his absence. Various resolutions in respect of the war were passed by the Senate, including amendments to the regulations for medical degrees, enabling students to count service with the Forces, or in hospitals or Red Cross detachments recognised by the naval or military authorities, as equivalent to hospital practice. An addition was also made to the Regulations for the M.D. and M.S. degrees, authorising a temporary commission during the war in the Royal Army Medical Corps or Royal Naval Medical Service to be held equivalent to an "approved appointment." Dr. E. Graham Little has been reappointed a member of the committee of the Chelsea Physic Garden; Sir David Ferrier has been elected chairman of the Physiological Laboratory Committee of the University; and Sir Alfred Pearce Gould has been re-elected Dean of the Faculty of Medicine for the period 1914–16. A University Medal has been awarded to John Lloyd Davies, B.S., on the result of the July examination for the M.D. degree (Branch I., medicine). On account of the war it has been decided to postpone the advanced courses in physiology, but the inter-collegiate courses in physiology will be given as announced.

On the occasion of the opening of Parliament on Wednesday the address in reply to the speech from the Throne was moved in the House of Commons by Sir Robert J. Price, M.P., who became a Member of the Royal College of Surgeons of England in 1876, and has represented the East Norfolk Parliamentary division for the past 22 years.

Royal College of Surgeons of England.—The annual general meeting of Fellows and Members will be held at the College, Lincoln's Inn-fields, W.C., on Thursday next, Nov. 19th, at 3 o'clock. A resolution will be moved by Sir Victor Horsley, and seconded by Mr. George Jones, affirming the desirability of admitting Members to direct representation on the Council of the College.

Medico-Psychological Association of Great Britain and Ireland.—The next general meeting of this association will be held on Tuesday, Nov. 24th, at 3.30 P.M., at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. David G. Thomson. The usual quarterly dinner will not take place.

Medico-Legal Society.—A meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday next, Nov. 17th, at 8.30 P.M. After an exhibition of specimens the President, Professor Harvey Littlejohn, will deliver an address, and Dr. Andrew Balfour, C.M.G., will describe Medico-legal Experiences in the Sudan.

National University of Ireland.—At the last meeting of the Senate of the National University of Ireland Dr. Joseph F. O'Carroll was elected to succeed the late Sir Christopher Nixon in the chair of medicine in University College, Dublin. Dr. O'Carroll had been assistant to the professor of medicine since the foundation of the University. At the same meeting Dr. John P. Henry was elected professor of ophthalmology and otology in University College, Galway; Dr. Adeline English lecturer in mental diseases; and Professor W. W. Brereton lecturer in operative surgery in the same college.

St. Luke's International Hospital at Tokyo.—It is reported that the Emperor of Japan has made a donation of £10.000 towards the foundation of St. Luke's International Hospital at Tokyo, promoted by the Episcopal Mission. The gift was announced by Count Okuma, the well-known statesman and leader of the Progressive Party, at a luncheon at which a number of prominent residents of Tokyo were present. The British Ambassador and the United States Ambassador supported the scheme, which is to cost £200,000. The interest shown by the Imperial Court towards the work of charity is conspicuous. The Court while professing neither Buddhism nor Christianity has given liberal donations to Christian and Buddhist philanthropic undertakings. The Japanese Red Cross Society, which assumed its present name in 1886 when Japan joined the Geneva Convention (although a forerunner of the society was started in 1877), is under the special patronage of the Imperial family, and the benevolence of the Court has been also extended to other works of practical charity.

The Protection of Hospital Buildings from Fire.—The hospitals and schools committee of the National Fire Brigades' Union have issued four pamphlets containing suggested precautions against fire and for extinguishing fire. These pamphlets deal respectively with hospitals, public schools, boarding schools, and elementary schools. No. 1, a copy of which has been sent to us, refers to fires in hospitals and ought to be in the hands of everyone connected with hospital administration whatever capacity he may hold; for just as the prompt rendering of first aid, pending the arrival of more skilled help, may save the life of a patient, so a knowledge of the right thing to do on the first alarm of fire may prevent a serious catastrophe. We note with approval that the union has offered to examine the staffs of hospitals and schools who are trained in fire drill and have decided to give any information or assistance, with the establishment of gear, &c., for the protection of life and property. Further information can be obtained from the offices of the union, 22, Northumberland-avenue, London, W.C.

The anniversary dinner of the Royal Society, which is ordinarily held on St. Andrew's Day (Nov. 30th), will not take place this year.

We regret to announce the death at the comparatively early age of 56 of Dr. Angelo Celli, professor of State Medicine in the University of Rome and director of the Hygienic Institute attached to the Medical Faculty.

A Centenarian.—Through Commander R. R. Hubbard, R.N.R., His Majesty the King has sent his congratulations to Captain Daniel Jackson, of Tooting, who will celebrate the 107th anniversary of his birthday on Nov. 20th.

Royal Faculty of Physicians and Surgeons.—At the annual meeting of Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow Dr. John Barlow, senior surgeon to the Glasgow Royal Infirmary, was re-elected president.

BOOKS, ETC., RECEIVED.

Baillière, Tindall, and Cox, London.

Indispensable Orthopædics: A Handbook for Practitioners. By F. Calot, Chief Surgeon to the Hôpital Rothschild. Translated from the sixth French edition by A. H. Robinson, M.D., M.R.C.S., and Louis Nicole. 8 plates and 1250 illustrations. Price 21*s.* net.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

A TOUGH DOG.

To the Editor of THE LANCET.

SIR,—Some time ago I was asked to supply a poison. This poison was to be administered to a large dog for having bitten a child; 20 grains of morphinæ mur. in rice were given to the animal. In about an hour the dog went into sleep, thence into a state of coma. This was about 9.30 P.M. The following morning the animal was still under the influence of the poison but not dead. So at 10.30 A.M. 6 drachms of Scheele's prussic acid was put down the dog's throat with the aid of a syringe. The effect was rapid breathing and a slight convulsive movement. The same afternoon the animal had a prowl round the garden. To-day the dog is running about the street "quite well." Now, can you tell me why the dog did not die? It might be possible for a big dog to "pull through" after such a dose of morphia. But how is it the prussic acid did not have the desired effect? I wonder if it would be possible for the morphia to prevent absorption of the acid, and by the time the dog was free of the influence of the morphia for the acid to have lost its strength, or would it be that the acid acted as an antidote to the morphia? I might mention I have poisoned dozens of dogs with prussic acid, but never before have I administered morphia previous to the acid. The acid was taken from a bottle that had not previously been opened. I should like to be enlightened on this subject.

I am, Sir, yours faithfully,

CHAS. OLLEY.

Port Elizabeth, South Africa, Oct. 6th, 1914.

INDIAN MILITARY TITLES.

A CORRESPONDENT writes: "With the advent of the Indian troops in Europe and the examination of the casualty lists, or lists of honour, we are brought face to face with the Indian military titles which are not quite so familiar in England as in India. For instance, in the infantry there is subadar or subahdar, equivalent to captain (really 'governor'); above him, however, is the subadar-major; jemidar, jemadar, or jamadar, equivalent to a lieutenant; havildar or hawaldar, equivalent to a sergeant; but there is also 'havildar-major,' a sergeant-major; naik, a corporal; and sepoy (which is akin to the well-known 'spahi' in the old Turkish army), equivalent to a private, sipahi meaning 'soldier.' In the cavalry a sowar or sáwár ('rider') is a trooper; the duffadar or dafadar, is equivalent to the sergeant; and the risaldar is the captain or commander of a troop of cavalry, a 'risala' being a troop of horses and 'dar' being the 'master, keeper or lord.' Above him is the risaldar-major, but immediately below him is the ressaidar and the jemadar."

FULL FLEDGED.

A CORRESPONDENT draws our attention to a paragraph in the *Aberdeen Press* of Nov. 3rd which, with the omission of name and town, runs as follows:—

> After a full course in practical and theoretical dentistry at the Royal College of Physicians and Surgeons, Edinburgh, Mr. —— ——, The Manse, ——, has attained the degree of L.D.S. Edinburgh.

No one wants to be over-critical in these days, but whoever sent this puff to the newspaper let enthusiasm get the better of discretion.

A FLEMISH PHRASE BOOK FOR NURSES.

A PAMPHLET of useful Flemish phrases for Red Cross work, for nurses, dressers, and other ambulance workers, similar to that on French noticed in THE LANCET of Sept. 12th, p. 728, has now been prepared, and can be had free on application (enclosing a stamp for postage) to Hugo's Language Institute, 64 and 66, Oxford-street, 35, Great George-street, 33, Gracechurch-street, and 205, Earl's Court-road.

H. D. F.—The conditions laid down for the appointment of surgeons for temporary service in the Royal Navy state that applicants must "engage for 6 months certain, but the liability to serve will be limited to 5 years." They will receive two calendar months' notice of services being no longer required, and voluntary resignation of appointment will be allowed subject to the convenience of the service, but the gratuity of two calendar months' pay on discharge will be forfeited in the latter case. It seems quite clear, therefore, that at the end of six months' service the temporary surgeon can, if he wishes, resign, but exactly when his resignation would become operative must depend on where he is stationed at the moment.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Mr. A. Mallock: Note on the Circulation of the Atmosphere.—Colonel Sir Sidney Burrard: On the Origin of the Indo-Gangetic Trough—commonly called the Himalayan Foredeep.—Mr. G. W. Walker: Approximately Permanent Electronic Orbits and the Origin of Spectral Series.—Mr. W. Jevons: Spectroscopic Investigations in connexion with the Active Modification of Nitrogen. IV., A Band Spectrum of Boron Nitride (communicated by Prof. A. Fowler).—Prof. E. Wilson: An Additional Note on the Production of High Permeability in Iron (communicated by Prof. J. A. Fleming).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

GENERAL MEETING OF FELLOWS at 5 P.M.

Ballot for the Election of Candidates to the Fellowship.

SECTION OF PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, C. Price-Jones): at 8.30 P.M.

WEDNESDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawfurd, Leonard G. Guthrie): at 5 P.M.

Papers:

Dr. Raymond Crawfurd: Oliver Goldsmith and Medicine.

Mr. Macleod Yearsley: Autograph of Joseph Ignace Guillotin, with Note on Error that he fell a Victim to his own Instrument.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.

Exhibition of Cases.

FRIDAY.

SECTION OF OTOLOGY (Hon. Secretaries—W. M. Mollison, E. D. D. Davis): at 5 P.M.

Cases and Specimens:

Will be shown by Dr. Wyatt Wingrave, Mr. C. E. West, Mr. E. D. Davis, Mr. W. M. Mollison, and others.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on Surgical Experiences of the Present War (opened by Sir Watson Cheyne, Bart.). Mr. A. Edmunds, Sir F. Eve, Mr. R. P. Rowlands, Mr. D'Arcy Power, Mr. C. Symonds, Dr. Embleton, Dr. I. Bruce, and others will take part.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Exhibition of Pathological Specimens and Cases. 5.15 P.M., Resumed Discussion on Dr. C. Mills's paper on Syphilis.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Paper:—Sir William Osler, Bart.: Enteric in War, with Means for its Prevention.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

TUESDAY.—10 A.M., Major Operations.

WEDNESDAY.—10 A.M., Obstetrical Lecture: The Treatment of Eclampsia. 11 A.M., Examination of Patients and Minor Operations.

THURSDAY.—10 A.M., Major Operations.

FRIDAY.—10 A.M., Gynæcological Lecture: The Use of Pessaries. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months ... ... —	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

ON

THE TREATMENT OF WOUNDS IN WAR.

Delivered before the Medical Society of London on Nov. 16th, 1914,

BY SIR W. WATSON CHEYNE, BART., C.B., F.R.S., LL.D. EDIN.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. PRESIDENT AND GENTLEMEN,—I propose to-night to limit my share in the discussion on "Surgical Experiences in the present War" to the treatment of wounds sustained from missiles. The treatment of these injuries naturally falls under two headings: (1) The treatment of the wound itself, and (2) the treatment of the various injuries which may be done to the structures or organs through which the missile passes.

It seems to me that at this stage of the war the most urgent and profitable heading to discuss is the first—viz., the treatment of the wound as a wound, apart from the other injuries which may be present. As regards the latter, we can as yet only speak of individual cases, which, however interesting to the surgeon himself, are not sufficiently numerous or advanced to enable us to make any fresh generalisations apart from those which have already been made in connexion with other wars.

THE CHARACTER OF WOUNDS IN WAR.

Naval wounds are practically entirely caused by fragments of shell or portions of the ship itself, broken up by the shells, and these produce large, ragged, lacerated wounds which cannot scab over, and where bones are injured they are very much broken up. We have not had from our ships a single instance of a bullet wound, but we had some bullet and also some shrapnel wounds among the marines from Antwerp. A considerable number of the wounds have also been complicated with burns, while in many cases there have been burns without any wound, as the result of the explosion of the enemy's shells or of our own.

In the case of the army a large proportion of the wounds are due to the sharp-pointed, narrow bullets, many of which pass through the tissues and leave only small apertures of entrance and exit which scab over and seldom require any treatment for the wound itself. Occasionally, however, for various reasons, the wound of exit may be large, in which case sepsis may occur there. The round shrapnel bullets make larger orifices of entrance and exit than the rifle bullets and do not so often scab over, while if they fracture bones the injuries are much more severe. The wounds with portions of shell resemble those met with in naval warfare.

Now, the first thing which strikes everyone who is actively engaged at the present time in the treatment of the wounded, whether on land or sea, is the great prevalence of sepsis. Giving my own experience of naval cases, *all the wounds which I have yet come across have been septic*, some of them very badly so. I hear also that those who are working at the army base hospitals are having a large amount of sepsis in shell and shrapnel wounds, and in addition, at first at any rate, while our army was located towards the centre of the line, were having a good many cases of tetanus and acute spreading gangrene. So far we have not had tetanus in the naval wounded, and that is of course natural, for seeing that the tetanus bacillus reaches wounds from the soil it is only those wounded on land who would get their wounds contaminated with this organism. And, probably for the same reason, I have not met with a case of acute spreading gangrene.

It is a very serious matter that all the larger wounds which arrive at the base are septic. It is true that in some the sepsis is not so severe as to threaten the life of the patient, but it is no light thing for a wound to become septic. Once get sepsis into a wound, especially a compound fracture or a wound of a joint, and you have no certainty as to what the result may be. The patient may lose his life from one or other of the septic diseases, or his limb may have to be removed in order to save his life. His convalescence will be prolonged and may be interrupted by the occurrence of fresh abscesses, while he will suffer much pain. He may be left with serious deformities from the difficulty of replacing parts or of keeping them in proper position on account of the septic wound; and as the result of the extension of the inflammation and suppuration to the various parts in the neighbourhood, structures become matted together, and great disability may ensue.

REASONS FOR SEPTIC CONDITIONS OF WOUNDS.

It is now exactly 50 years ago since Lister formed the opinion that the cause of septic wound troubles was the entrance of bacteria into the wounds, and since he first put that idea to the test in a case of compound fracture. And in that case he saw for the first time in his experience a compound fracture following the course of a simple fracture and not undergoing suppuration. His earliest communication on the subject of the treatment of wounds dealt with compound fractures, most of them severe cases and much soiled, and he was able to record a number of aseptic results and to observe various phenomena, such as the organisation of blood clot, which only occur in an aseptic wound. During the rest of his active life he had to treat many compound fractures and other serious injuries, and with some exceptions, to which I shall presently refer, he obtained aseptic results.

You may well ask then, Why are we not having the same experience here to-day? Why are all the large wounds which reach us from the front in a septic condition? For this there are several reasons.

One very important point which affects this question of asepticity in these wounds is the length of time which may elapse after the injury before the patient comes under treatment. The conditions in the army and the navy are very different from those in civilian practice. In the latter the patient can generally be attended to within a very short time after the infliction of the injury, and can be transported quickly to his own home or to a public or private hospital, where the immediate and subsequent treatment can be at once carried out under the most favourable circumstances and without any further movement of the patient.

The Wounded in Army and Navy.

In the case of the army the wounded must lie where they fall, and cannot be attended to perhaps for many hours. Formerly, where there was not such a terrific hail of missiles over the field of battle, and where, perhaps, a greater feeling of humanity existed, and where also the distances

No. 4760.

between the combatants were not so great, the Army Medical Corps went out with ambulance wagons and were engaged during the progress of the battle in ministering to the wounded and in picking them up and removing them to a region of comparative safety at a short distance away. The ambulance wagons and depôts for first aid were respected as far as possible by the combatants, and though the members of the Army Medical Corps exposed themselves to great dangers, still it was possible in many cases to commence the treatment of the wounded comparatively soon after the infliction of the wound; and, further, battles were over usually in a few hours. At the present time the condition of matters is quite different. In many instances it would be madness to attempt to pick up the wounded while the engagement is going on, not only on account of the tornado of missiles, but also because the combatants are often too far apart for the Red Cross badge on the arms of the men, or even on the wagon, to be recognisable, even if it were respected. Besides, the presence of the wagons and men wandering about the field might give important information as to the position of the combatants. The result is that the wounded often cannot be attended to for a long time; sometimes, indeed, we hear of 48 hours or longer having elapsed before they are collected, and in the meantime the wounds are becoming more and more infected. It is true that where a medical officer is present in the trenches he may be able to do a little, but only very little, in the way of treatment.

Again, when the wounded have been collected, they must nowadays be removed for a considerable distance, sometimes a good many miles, to the field or temporary hospital, and naturally, with enormous numbers of wounded, this transport cannot be carried out in a particularly expeditious or comfortable manner. Even at this field hospital the patient is not at rest; he can only remain there while those parts of the treatment that are most essential are carried out, and then he is sent on to the base. At the field hospital, however, the treatment of the wound itself can be carried out, at any rate in the more serious cases, but in a good many it is not till the patient reaches the base that full attention can be paid to the injuries caused by the missiles.

In the case of the navy the conditions are also very unfavourable. In the old days the wounded were carried down from the deck to the surgeon's quarters as soon as they fell, or very soon afterwards; nowadays the surgeons and non-combatants on a battleship are all kept below, and only those actively engaged in the fight are on deck, and consequently the wounded must lie where they fall till the battle is over, or at any rate till a lull in the fighting occurs. From the battleship the wounded are transhipped as soon as possible to the carrier or hospital ship, from which again they are transferred to the hospital at the base, but the treatment of the wounds can be commenced as soon as they get on board the carrier or hospital ship. So far the wounded have been sent back to the base in a destroyer or other quick war vessel, but this is very unfortunate for them, as a doctor is not, as a rule, carried on board a destroyer, and little or nothing can be done for them during the transit—at any rate, in the way of remedying sepsis. It seems to me that, wherever possible, a hospital ship should be in the neighbourhood of the action, and the badly wounded should be taken on board it as soon as possible, or, if this is not advisable, doctors, orderlies, and dressing materials should be transferred to the destroyer so that the treatment of the wounds may be commenced at once. The position of the hospital ship and the transference of the wounded are, of course, matters dependent on the military necessities of the case, but the commander should always have present in his mind the supreme importance of the immediate treatment of the wounds and the inadvisability of allowing several hours to elapse before they can be attended to. The point is not the speed with which the wounded can be got ashore; it is the earliest time that treatment can be commenced, and this, of course, can be begun at once on board ship if the necessary means are at hand, however slowly the vessel proceeds to the base. The naval wounded have therefore an advantage over the army, in that the wound is not so much soiled and can, as a rule, be attended to sooner; they have the disadvantage that the wounds as a whole are more severe.

Now, as I shall presently point out, the chances of rendering a wound aseptic are comparatively small after 24 hours, and practically *nil* after 48 hours; indeed, after that time I should not make any attempt to disinfect the wound. If, therefore, the case does not come under treatment within 24 hours I do not think that we can blame any surgeon or any system of treatment for the septicity of the wound. In spite, however, of the above disadvantages, a considerable number of cases do come under suitable conditions for treatment within the period of time that I have laid down, and that being the case, a certain proportion of these patients should reach the base with aseptic wounds.

Disinfection of Wounds.

This leads us to the question of the disinfection of the wound, a branch of wound treatment which I fear is but little taught in the schools. Lister's experience and practice in this matter are forgotten, if, indeed, they are now known. The omission really arises from the want of precision and the carelessness which are creeping into the treatment of wounds at the present time. I do not make this as a universal charge by any means. There are many surgeons who take the very greatest care, whose operations it is a pleasure to watch, and whose results are excellent. But there are many others who do not seem to have got a proper grip of the matter, and whose results leave much to be desired. They follow the fashion in having a well-finished operating theatre, in dressing themselves up in the most approved and elaborate fashion, and in having instruments and dressings sterilised; but they end there. They forget the ubiquity of bacteria, and that their instruments, gloves, &c., may lose their sterility during the course of the operation; they deride antiseptics. If suppuration occurs in the wound afterwards they ascribe it to all sorts of causes, such as the silk, catgut, migration of bacteria, gout, influenza, &c., rather than the real cause—viz., their own faulty manipulations; and their example is naturally followed by those whom they teach.

"Asepsis" and "Sterilisation."

In one of my books I placed at the beginning as a motto the following sentence: "Suppuration in a wound made by a surgeon through unbroken skin is due to some error on the part of the surgeon." This gave great offence, but it is absolutely true, and unless a man takes that view and searches his own procedures when things go wrong in order to see where the error was, I quite despair of his ever being a trustworthy aseptic surgeon. To exemplify the carelessness which is not uncommon in the treatment of wounds, I could entertain you for the rest of this meeting by telling you the quaint things which are done by those engaged in operations, and the constant opportunities which are afforded for the entrance of bacteria during an operation, and the crude ideas which are abroad as to "asepsis" and "sterilisation." Watch the course of one of these so-called aseptic operations from a bacteriological point of view and you will see all sorts of errors and omissions which pass unnoticed, and these have led to a large literature on stitch abscesses, bad catgut, migration of bacteria, and so on.

I saw an operation the other day; everything had been sterilised, a dry sterilised towel was spread out on a table, the boiled instruments were turned out on this towel, and were then arranged by a nurse who did not wear a mask. Something excited her attention, two other nurses came up, also unmasked, and the three became agitated, all bending over the instruments and talking at the same time; people were coming and going, and at least 20 minutes elapsed between the time that the instruments were turned out and the commencement of the operation. Were they still aseptic? And yet the surgeon comes in completely booted and spurred, innocently picks up a knife and goes on with the operation. Is it any wonder that that surgeon has a good deal to say about catgut, silk, and so-called stitch abscesses?

I am always very suspicious of so-called sterilised towels and swabs, especially in work in private. They are often placed in a sort of potato steamer for a few minutes, an apparatus which would take hours to cook a potato, and therefore if I do not know the nurses I always order the towels to be boiled in a pan for half an hour and not touched before I arrive. Well, in one case nurses were sent out from a large aseptic hospital who were said to be fully trained and most excellent. They received my instructions about the towels, and on my arrival I found a very small poky room with very few dishes in it (not the palatial apartments in which some of my more fortunate *confrères* are accustomed to operate). I looked about for my towels, but could see no trace of them. I therefore called the nurse and asked her for them. She lifted the lid of the commode and there were my aseptic towels reposing at the bottom of the night-stool—another source of coli infection of wounds which is worth remembering.

A fresh instrument is wanted during an operation, or an instrument falls on the floor. It is popped into some boiling water and presented to the surgeon "sterilised" within a minute! and so on. A surgeon is doing an intestinal anastomosis, clips away mucous membrane, rinses his scissors in some salt solution leaving the tags of mucous membrane and portions of fæces in the basin, and when his hands become sticky rinses them in the basin repeatedly during the course of the operation. When an abscess containing bacillus coli forms he is much interested and refers to the remarkable habit that coli bacilli have of wandering through the coats of the intestine in cases of intestinal anastomosis, separation of adhesions, &c. This pernicious habit of the bacillus coli seems to be particularly common in operations in the pelvis. It never seems to occur to the surgeon that he has introduced the sepsis during his operation and that migration of bacteria, if it occurs at all, only takes place through the inflamed wall of the intestine.

I think the man who annoys me most is the boiled water man! Some surgeons seem to take a particular pride in emphasising their contempt for antiseptics and the extreme simplicity of their methods. A surgeon comes to an operation and finds a dish containing some fluid. He asks what that is, and the nurse who has been carefully trained in real aseptic work says, in fear and trembling: "That is carbolic lotion for your instruments." It is most instructive to see the look of contempt on the surgeon's face as he says: "Carbolic lotion! Who on earth uses antiseptics nowadays? I thought that no one out of an asylum ever thought of them. Take it away and give me a bowl of boiled water." He does not disinfect his hands but trusts to the protection of boiled gloves, which, however, are soiled at the very beginning by being put on with unsterilised hands. He thinks that he is no end of a great man, and the unfortunate thing is that the nurses and students think so too and follow his fatal example. I wonder whether, if such a man had a son at the front at the present time, he would feel happy in the thought that the only thing which the surgeon had at hand for the treatment of wounds in war was a basin of boiled water! Faugh! The futility and littleness of it all make me sick.

Importance of the Bacteriological Problem.

The result of this slackness is that a good many men are being sent out from the schools every year who are not impressed with the bacteriological problem involved in the treatment of wounds, or who have come to believe that no such problem is involved, while they have become thoroughly impregnated with the idea that the use of antiseptics is an abomination, and that no surgeon who has any self-respect left or who is not in his dotage would ever think of using them. When they are confronted with soiled wounds, such as occur on the field of battle, they do not know what to do or how to proceed beyond painting the skin with iodine and covering the wound with a piece of gauze. The consequence is that the bacteria get a firm hold on the tissues before any means which might have been efficient in the first instance can be adopted. Hence the results which Lister obtained with compound fractures at the very beginning of his work 50 years ago, and which he continued to obtain subsequently, are not being met with in the present war.

The answer then to the question, why do practically all wounds in the present war become septic? is threefold: (1) because there is often long and unavoidable delay in collecting the wounded and commencing treatment; (2) because the wounds may be very large and complicated and almost impossible to disinfect thoroughly; and (3) because in a good many cases no attempt is made to disinfect these wounds, or if it is made it is utterly inefficient.

How, then, should the large open wounds which occur in warfare be treated? The treatment of these wounds may be considered under two headings according to the time at which they come under the notice of the surgeon—viz. (1) those which can be treated during the first 24 hours after their infliction: and (2) those which are only met with at a later period, when sepsis and suppuration are already established.

I. Treatment of Wounds which come under the Surgeon's Care within the first 24 Hours after their Infliction.

Let us consider the condition of such a wound from a bacteriological point of view, and here I shall only speak of the larger wounds sometimes caused by bullets and wounds caused by fragments of shell or by shrapnel bullets. Wounds due to the modern small bullets, when they pass directly from one side of the body to the other without injuring bone or becoming deflected, are very small and sometimes difficult to find, and usually scab over and close without any further attention than a piece of dry dressing, unless some important internal structure has been injured.

Rapid Growth of Bacteria in Wounds.

With regard to the larger wounds they must, of course, be widely infected with bacteria at the time of their infliction, at any rate to a considerable depth; and not only is the wound infected at the moment of injury by the bacteria carried in from the skin and clothing by the fragment of shell, but it very rapidly becomes much more seriously infected by dirt from the clothing or from surrounding objects, and in the case of land warfare, by the soil of the place in which the wound is inflicted. These large wounds are consequently infected with all kinds of bacteria, not only with naked, easily killed organisms, but also with highly resistant spores, the latter being most common and most dangerous in wounds soiled with earth. These organisms are not only lying free in the cavity of the wound and thus apt to be washed away by the blood, but they are also adherent to the tissues which form the sides of the wound, if indeed they have not been actually driven into them. These bacteria, finding themselves in a highly nutritious soil and at a suitable temperature and with plenty of moisture, at once begin to sprout and multiply with great rapidity. I do not know how long it would take a spore to sprout in the first instance, but I do not suppose it would be any great length of time; but once they have sprouted, they multiply rapidly. Many organisms divide and double their numbers within 20 minutes. At that rate, it does not take long for a wound to be filled with myriads of organisms. Suppose we take it that each organism divides in half an hour, that would mean that each organism gives origin to 15 million at the end of 12 hours. Further, not only do these organisms multiply in the fluids which are free in the wound, but being in contact with weakened or dead tissues, the pathogenic varieties soon penetrate into the tissues and establish themselves there. Within the first 24 hours, therefore, we may take it that the state of matters is that the fluids in the wound are already teeming with actively growing bacteria, and that they have also penetrated into any pieces of dead tissue on the surface of the wound and to a slight extent into the living tissues forming the wall of the wound. Once they have penetrated into the tissues they establish themselves there and are extremely difficult to dislodge.

Eradication of Sepsis.

Now it is evident that the only efficient way of dealing with such a state of matters is to destroy these organisms which have entered the wound as soon as possible and before they have had time to grow and establish themselves firmly in the tissues, bearing in mind the fact that every hour that passes they quadruple their numbers at the very least. This will not be done by painting a little iodine over the skin around, or even by pushing it in among the blood, and by covering the wound with a piece of aseptic gauze; very much more careful and vigorous treatment is required than that. And it should be in the mind of every man who deals with these wounds that the ultimate results depend to a large extent on the prevention of sepsis; these results concerning not only the life of the patient, but also the rapidity and smoothness of his convalescence and his later condition.

As to the period of time during which it is advisable to attempt disinfection of the wound, my opinion is that it is only during the first 24 hours that it is at all likely that bacteria can be eradicated, and indeed after 12 hours the result is not at all certain. During the first 12 hours, however, the great majority of wounds, unless they are large and irregular or complicated with extensive comminution of bone, can be quite readily and immediately rendered aseptic, and if proper precautions are taken afterwards will remain aseptic, and thus the whole troubles resulting from the primary soiling of the wound will be avoided. Even up to 24 hours the infection can be rooted out in a considerable percentage of the cases. In the circumstances under consideration where wounds are soiled with earth, and where therefore there is considerable danger of tetanus and gangrene, I think that the period during which an attempt at disinfection should be made might be prolonged up to 48 hours. After that time the disinfection will certainly fail, and the attempt will do more harm than good by injuring the tissues which are opposing the invasion of the bacteria and thus enabling the infection to spread more easily and rapidly. Hence I would lay it down as an axiom of practice in the class of wounds under consideration that if the treatment can be carried out within the first 24 hours (and in the case of wounds soiled with earth 48 hours) an attempt should be made to kill the organisms which have entered the wound. These organisms can only be got rid of by means of chemical antiseptics. I fear that, try how you may, you cannot avoid their use.

Two points must be taken into consideration in making this attempt. The first point is, that we have not only to kill actively growing bacteria, but also the spores of bacilli, seeing that some of the latter class of organisms are highly pathogenic. For example, the tetanus bacilli and various other bacteria which cause pathogenic processes, such as some forms of gangrene, are spore bearing, and are thus extremely resistant to all destructive agents. Hence, the agents we use must be sufficiently potent to kill spores under whatever circumstance they are found, whether dry or in albuminous or oily materials. And the second point is that these spores must be killed quickly because one cannot keep such potent agents for any length of time in contact with the tissues, otherwise they may destroy them, and furthermore, these agents, if absorbed into the system, are all more or less poisonous.

Antiseptic Agents.

There are three potent antiseptics in common use at the present time—viz., carbolic acid, bichloride or biniodide of mercury, and iodine. Of these, we may exclude the mercurial salts, because although they kill microbes quite readily and in very considerable dilutions, if these organisms are free or in a slightly albuminous fluid they are of no use when the organisms are present in albuminous or oily substances. In the case of the former, mercury combines immediately with the albumin, forming a compound which possesses very little antiseptic power; and as regards the latter, these salts do not dissolve in oil, and therefore organisms lying in oily material are not reached by the antiseptic. We are therefore left with the two substances, carbolic acid and iodine, and we must now consider these substances and determine which of them is best and most suitable and in what strength they should be used.

(*a*) *Carbolic acid.*—A saturated watery solution of carbolic acid (1 in 20) will kill naked, actively growing bacteria in a few seconds, but will not kill spores with certainty under from 12 to 15 hours, and this time will be still further prolonged if these spores are present in albuminous or oily material, because a certain amount of the antiseptic power of the carbolic acid is lost in combining with these substances. It is evident, therefore, that washing out the cavity of the wound with 1 in 20 carbolic lotion will not disinfect it if it contains the spores of pathogenic bacilli. On the other hand, liquefied carbolic acid will kill spores in a very few minutes—as soon, in fact, as it can soak into them. And therefore, if carbolic acid is to be employed in wounds soiled with material such as earth containing pathogenic spores, it must be used in the form of liquefied carbolic acid. Carbolic acid precipitates and combines with albumin, but the compound is still strongly antiseptic. It also dissolves readily and in large amount in oil, still retaining its antiseptic property, though not so strong as in watery solution. (1 in 10 oily solution is about equal antiseptically to 1 in 20 watery solution.) Hence the presence of oil does not protect the bacteria. This is the chief reason why I prefer carbolic acid for the disinfection of the skin rather than any other antiseptic, because it dissolves in the natural oil of the skin and so can extend its antiseptic action down the hair follicles and the orifices of the sebaceous glands. Further, carbolic acid is an anæsthetic, and its application causes very slight pain which subsides almost immediately.

(*b*) *Iodine.*—The antiseptic power of iodine is practically the same as that of carbolic acid, so that the 2 per cent. solution in common use is of about the same value as 1 in 50 carbolic lotion. What the effect of a 5 per cent. solution of iodine or of still stronger iodine would be on the tissues I do not know, but I fancy it would be intensely irritating, to say the least. Even with the 2 per cent. solution the skin must be dry before it is applied, otherwise it is very apt to be blistered, and the antiseptic properties of the iodine solution are said to be diminished. How it could be used in the field with the impossibility of drying the skin and keeping it dry I do not know, and I have been told that there have been several cases of iodine burns of the skin where this antiseptic had been employed.

Further, iodine causes great pain which lasts for a considerable time, as is well known in connexion with the iodine treatment of hydrocele. When I was a student the treatment of hydrocele was the injection of a strong solution of iodine, and the agonies which the patient suffered afterwards, and the pain and the inflammation which lasted for some days, was in very marked contrast to the painlessness and absence of inflammation which follow the injection of carbolic acid. Hence, although I may be thought not to be up-to-date, I still prefer carbolic acid to iodine, not only for the disinfection of the skin, but also, and more especially in the circumstances with which we are dealing—viz., as a means of destroying the bacteria which have already entered wounds before they come under the care of the surgeon. I am not, however, prepared to say that a sufficiently strong preparation of iodine might not possibly effect the same purpose, but in a few cases which I have seen in which iodine has been applied to the wound, it had not prevented the sepsis. Personally, if I had a wound I should insist on the use of carbolic acid in preference to iodine, both from the point of view of efficiency and of comfort.

Other antiseptics have been suggested, but none of them are sufficiently potent for the cases under consideration. Of these, peroxide of hydrogen seems to be a favourite abroad, but its antiseptic power is comparatively weak and it would be useless against spores.

Lister's First Work.

Before describing the details of the procedure to be adopted in disinfecting a wound let me recall Lister's first work and our subsequent experience. Lister's first attempt at aseptic work was by the use of a crude solution of carbolic acid called German creasote, so impure that at first he thought that carbolic acid was insoluble in water. For a time his experiments were only made on compound fractures, of which a large number, some of them very serious, occurred in Glasgow, where he was located at that time. His original plan was to introduce a piece of lint soaked in this crude carbolic acid into the wounds and thoroughly rub it into the recesses, and then to put in some more carbolic acid and stir it up with the blood so as to form a sort of paste which filled up the wound. Every day he painted a little carbolic acid over this coagulum, and in order to diminish the evaporation of the acid he covered the clot with a piece of block tin. Ordinary towels were then applied around to catch the discharge which soaked through; no other dressing was employed.

What was the result? All the cases followed an aseptic course so long as he continued the application of the carbolic acid; there was no temperature, no inflammation, no sloughs separating, no poisoning—in fact, none of the dreadful things which students are led to believe will result from the application of carbolic acid. No doubt in some cases where the carbolic acid was in contact for some time with the skin a small superficial slough formed which, however, was of no consequence. After a time, when he peeled off the superficial layer of the clot he found a healed, or almost healed, wound beneath. And as showing the absence of any injurious effects, it was in cases so treated that he first observed and demonstrated how blood clot if aseptic acts as a mould for the penetration of cells and for the formation of new tissue—what is now known as healing by blood clot. In some of his cases he discontinued the application of the carbolic acid after the deeper part of the wound had healed and when there was only a superficial sore, and as he had not devised any antiseptic dressing then he employed the ordinary dressings which he had previously been in the habit of using. Two or three of these cases showed septic troubles after the carbolic acid was left off, and, indeed, phagedæna occurred at this late stage, thus affording additional proof of the protective effect of his new treatment. I would recommend those who hold up their hands in horror at the idea of applying liquid carbolic acid to infected wounds to read and digest Lister's early papers.

Development of System.

As he developed his system, and found that carbolic acid was soluble and active in oil and water, he modified his plans, and later his method was to wash out compound fractures thoroughly with 1 in 20 carbolic acid lotion, taking measures to see that all recesses of the wound were subjected to its action. With this second plan the majority of compound fractures also remained aseptic, but a certain proportion did not do so, these results differing therefore from those which he obtained in the early days with the crude carbolic acid; these failures chiefly occurred in wounds which were badly soiled. We now know the reason of this—viz., that the dirt may be so ground into the tissues that the carbolic solution does not penetrate it thoroughly, and further that the 1 in 20 solution does not kill pathogenic spores in a short time. This led us to remove all visibly soiled portions of soft tissues or bones and to apply liquid carbolic acid to these surfaces, using the 1 in 20 lotion for the rest of the wound, and this diminished the number of failures, and this is the plan I adopt in civilian practice. I believe that this plan would be quite satisfactory in the majority of wounds in war, but where they are very badly soiled with earth, as is so often the case at present, we should, I feel sure, revert to Lister's original plan in so far as to paint the whole surface of the wound with liquid carbolic acid, with the exception, perhaps, of narrow tracks in the deeper parts. Certainly this ought to be done in all cases of compound fracture.

In carrying out the disinfection of the interior of the wound not only must it be done methodically and thoroughly, and all the recesses of the wounds carefully attended to, but one must not forget that it is most important to disinfect the surrounding skin most carefully. It is useless to disinfect the interior of the wound and to leave bacteria on the skin free to multiply there and spread in and infect the wound again. I also think it is best to *begin* with the disinfection of the skin. Again, one great difficulty in obtaining proper disinfection of a wound is the constant flow of blood from the wound which dilutes and washes away the antiseptic, and steps must be taken as far as possible to arrest or control the hæmorrhage in the first instance; this is a very important point. It may also be necessary to open up the wound, not only in order to arrest the bleeding, but also to reach all the recesses of the wound for the purpose of disinfection. Further, the process is painful, and therefore I should advise that in all cases an anæsthetic should be administered.

Method of Disinfection of Wounds.

The procedure would be as follows. The patient having been placed under an anæsthetic, the first thing is to control the bleeding. In the case of an extremity a tourniquet is applied, but where the wound is situated in the trunk any visible bleeding points should be clamped and the wound temporarily stuffed with gauze or large sponges. The next step is to cleanse and disinfect the skin thoroughly. In the first place scrub it thoroughly with 1 in 20 carbolic lotion and ether soap, then shave it, and finally wash it thoroughly again with the carbolic lotion, leaving a cloth saturated with the lotion over the whole area, so as to continue the disinfecting action and protect the skin while the interior of the wound is being attended to. The interior of the wound must now be disinfected, and if it is necessary to gain access to the deeper parts in order to enable one to see what one is doing, which is very important, the wound must be enlarged by incisions made in suitable directions. The blood must be thoroughly swabbed out, the wound made as dry as possible, and the skin or fat or other structures which are visibly soiled with earth or dirt should be cut away. The wound being then held wide open by retractors, a piece of sponge dipped in the liquefied carbolic acid is carefully and thoroughly applied to the whole surface of the wound and to all the recesses, care being taken, by holding a swab in the other hand on the edge of the wound, to prevent the acid running over the skin. It is well to sponge out the wound after the first application, and then to apply the acid a second and even a third time if there is bad soiling. If at the bottom of the wound there is a long narrow track leading to the tissues, it may not be necessary to disinfect it along its whole length, because the probability is that the bullet or fragment of shell does not carry the organisms in to a very great depth. If it is a large wound which has to be soaked with the undiluted carbolic acid, it may be well, after about 5 to 10 minutes, to wash it out first with 1–20 carbolic lotion and then copiously with saline solution, so as to get rid of the excess of carbolic acid and thus reduce the chance of absorption.

Having completed the disinfection of the wound, the tourniquet is relaxed, the vessels tied, and a good-sized drainage-tube inserted down to the bottom of the wound, or even through a counter opening if there is any doubt as to the thoroughness of the disinfection. Any incisions made by the surgeon may be closed by stitches, but no attempt should be made to stitch up the original wound, unless possibly where flaps of skin have been turned to one side, in which case they may be brought roughly into position by two or three stitches. After the disinfection of the wound is complete it is well to give the skin around an additional wash with the carbolic lotion, in case it may have again become soiled from the wound.

In the case of a wound on the trunk or neck where no tourniquet is available, and where therefore the bleeding cannot be thoroughly checked, the disinfection is much more difficult and uncertain, because blood is constantly washing away and diluting the antiseptic. Hence the first thing to be done under these circumstances is to open up the wound and try to check the bleeding by clamping any bleeding points; these, however, must not be tied at this stage. The wound should then be firmly packed with gauze, so as to check the capillary oozing. Having done this, the skin around is cleansed and disinfected in the manner already described, and attention is then turned to the wound itself. The plug is then taken out and a smaller one substituted, so as to leave the skin and subcutaneous tissue exposed to view. The surfaces so exposed are then dealt with in the manner already described, badly soiled skin and fat being clipped away and the surface thoroughly soaked with the antiseptic. Further portions of the plug are then removed so that the whole surface of the wound may be disinfected bit by bit; in addition it is well to irrigate it thoroughly with 1 in 20 carbolic lotion, and then, if large, with salt solution. Finally, the vessels are tied, and in doing so it is well in the first instance to take off the forceps one by one, daub the vessel with carbolic acid, catch it again with clean forceps, and then tie it. The rationale of this procedure is that the piece of tissue caught by the forceps has not been disinfected, and if it were tied at once a septic point and ligature would result.

In both cases after the disinfection is complete an antiseptic dressing (not merely an aseptic one) should be applied. The reason for using a dressing containing an antiseptic is that in the first place aseptic dressings are seldom available on the field of battle, and in the second place it may not be possible to change the dressing for some time, and if a non-antiseptic dressing is used the discharge passes through it and bacteria rapidly develop in it and reach the wound. On the other hand, a dressing containing an antiseptic which is soluble in the serum may give enough of the antiseptic to the serum to render it an unsuitable medium for the development of organisms, and thus, if the dressing cannot be changed early, an aseptic result may still be obtained. I believe that wool impregnated with salicylic acid is the best for this purpose, but it is well to put a piece of cyanide gauze (which is itself only feebly antiseptic) over the wound, so as to keep the salicylic acid from the skin.

It takes a long time to describe this matter, but it is perfectly simple, and I have adopted this method of dealing with compound fractures and other open wounds for years with a very large measure of success, and I should be very much ashamed if any considerable number of cases which came under my care within 12 hours after the accident did not follow an aseptic course. If iodine is preferred I cannot say what strength should be used, but it certainly ought to be much stronger than the ordinary 2 per cent. solution which is the favourite at present. The procedure would be the same as I have already described. If iodine is used instead of carbolic acid for the disinfection of the skin, it should not be applied directly over the dirty skin, and therefore, here also, the skin must be thoroughly washed and shaved and dried, first with a dry cloth and then with acetone. The trouble is that the skin will soon be wet again with the blood and serum when the wound is taken in hand, and not only is the disinfection imperfect, but the skin painted with iodine, if again wetted, is liable to be much irritated. I have not the slightest hesitation in saying that the disinfection will be much more thoroughly and satisfactorily done with carbolic acid, with less loss of time and also with less irritation of the skin.

Local Disinfection and Other Methods of Treatment.

The proper disinfection of a wound cannot be carried out in a hurry, and unfortunately in the army it will not be till the patient has arrived at the first field hospital, and in the navy, till the patient reaches the surgeon's quarters on the battleship or the hospital ship itself, that it can be taken in hand thoroughly. Whether anything can be done in the field or trenches which might help to delay or circumscribe the sepsis is a problem well worth considering. The first dressings with which the soldiers are provided are of no use except to prevent the entrance of further dirt, and the surgeon cannot be expected to carry with him the necessary arrangements for disinfecting the wound, though he might carry some antiseptics which might be introduced into the wound. Thus we have been trying at Chatham to make soluble bougies or suppositories, each containing 1½ grains of carbolic acid, which might be pushed into a wound before the emergency dressing is applied, or the surgeon might be provided with strong iodine solution, and pieces of gauze soaked in this solution might be pushed into the wound and left there. No thorough disinfection can, however, be carried out till the patient has reached some place (field hospital or sick bay) where he can rest for some time and where the methodical disinfection of the wound can be undertaken. As soon, however, as the patient has arrived at such a place the wound should be disinfected thoroughly, whether anything has been done previously or not. Even at the field hospital or sick bay it may not be possible to keep the patients long enough for all the wounds to be thoroughly disinfected, but at any rate all compound fractures and wounds of joints which do not require amputation and all wounds badly soiled with earth should be dealt with as far as possible.

At the present moment great stress is being laid on the particular kinds of organisms which may have entered the wounds, but very little is said about disinfecting the wounds. Instructions are being given, as regards the army, that immediately the patient comes under treatment he should have a subcutaneous injection of antitetanic serum and another of polyvalent antisepsis vaccine. Now I cannot speak with any authority as to the prophylactic value of antitetanic serum when injected into the subcutaneous tissues, but although *subcutaneous* injections of this serum are of no value in the treatment of tetanus once it has developed, those who have worked at the subject state that subcutaneous injection of the serum is of value if used immediately on the occurrence of infection. As regards antisepsis vaccine as a prophylactic, I am very sceptical indeed. It may possibly modify the severity of the impending sepsis, but I feel sure it cannot be depended on to prevent it. At the same time, we must not disregard any possible safeguard, and for the present I think it is well, in military surgery at any rate, to inject these substances in the manner which has been advised. I should not think that it is necessary in naval surgery to inject antitetanic serum.

I do hope, however, that those who have to treat these wounds will not take it into their heads that after making these injections they have done all, or indeed, anything of any real importance for the safety of the patient. I am very much afraid that some men will be satisfied with these injections, and will take no further local steps to render the wound aseptic, and will look on these injections as a way of avoiding the use of the much-hated chemical antiseptics. By all means use these injections, but never lose sight of the fact that the only trustworthy way of avoiding the septic diseases which inevitably follow these wounds is to kill the organisms before they have taken root in the body. Remember also that we have not to do only with one species of organism; we have to do with a great many, and even if the methods suggested were as effective as we could hope it leaves many other organisms untouched.

II.—TREATMENT OF WOUNDS IF MORE THAN 24 OR POSSIBLY 48 HOURS HAVE ELAPSED SINCE THE INFLICTION OF THE WOUND.

It may happen that patients cannot be treated within the period above mentioned, and the question then arises whether any attempt should be made to disinfect the wound in the manner above described. By this time the organisms will, for the most part, have got a firm hold on the tissues, and any attempt to get rid of them by antiseptics will fail, and if the attempt fails at this stage it may cause a great deal of harm by injuring the actively granulating tissues. It may possibly be well still to clip away any visibly soiled tissues and touch the raw surfaces with liquid carbolic acid, but I think that any attempt at general disinfection of the wound would be a very injudicious and harmful procedure, and still more so if suppuration has begun. Indeed, I would go further and say that not only should strong antiseptics be avoided, but also even weaker ones. I usually find that surgeons get busy syringing out these early septic wounds with various antiseptic lotions, and not only on the first occasion but every time the dressing is changed, and I consider this to be very bad practice indeed.

The Relation of Antiseptics to Wounds.

In fact, my views on the relation of antiseptics to wounds are exactly the opposite to those in vogue at the present time. It may be that I am not up to date, but I fancy that I have perhaps been trained to take the treatment of wounds more seriously than most people, and to think and work a great deal at it. My own view is that if a wound is aseptic, while I do not willingly put antiseptics into it, their entrance will not interfere with healing at all so long as no bacteria have been let in by the surgeon. But on the other hand, if bacteria are already established in a wound, I think it is the worst treatment possible to meddle with it more than one can help, and more especially to syringe it out with antiseptics and to poke gauze and other things into it. The general practice at present is just the reverse—viz., to avoid antiseptics when the matter is of no consequence and when their use outside the wound may help to prevent the reinfection of instruments and materials used; and, on the other hand, to use them when the wounds are septic, when they cannot kill the bacteria, and when the only effect they can have is to damage the natural defences of the tissues. The chief antiseptic which I would use in septic wounds, and that only in foul-smelling ones, is peroxide of hydrogen, which, although a feeble antiseptic, certainly seems to overcome the fetor and does not irritate the tissues to any marked degree. If it is deemed advisable to wash out a septic wound, use normal saline solution as a rule, though very weak antiseptic lotions may do no noticeable harm, once granulation is fully established.

I believe that the chief reason for the present prejudice against antiseptics was the free use of these lotions formerly by surgeons who deluged their wounds with antiseptics, but took no care as regards disinfection of hands, skin, instruments, &c., and infected their wounds thereby, at the same time damaging the resisting power of the tissues by their antiseptics. The result was that the wounds did badly, but not, as they thought, as the direct effect of the antiseptic, but from the introduction of bacteria into the weakened wounds. They thought they were practising Listerism, and therefore gave it a bad name, but they were not following the master's teaching. I remember in the old days of the carbolic spray remarking to Lister more than once that while practically all our wounds healed aseptically, yet if a wound did go wrong with us, it went wrong worse than in the hands of septic surgeons. The reason was that the irritation of the spray diminished the local resisting power, and so enabled the organisms introduced to grow more readily; if no organisms were introduced this temporary diminution of local resisting power did not matter. It is curious how difficult it is to make people understand that carbolic acid or other antiseptic is not used as an application to a wound, but as an application to the bacteria outside the wound. The healthy tissues are sterile, as I was the first to demonstrate many years ago, and they need no antiseptic application to them; the enemy, the bacteria, come from without and should be killed outside the wound.

Drainage of Wounds.

As the wounds have come to us at the base hospital they are not only septic but they are often imperfectly drained. It is therefore necessary in most cases of large wounds, and especially where bones or joints are injured, to interfere with them by operative measures on their arrival at the hospital, but this should be done, as far as possible, once and for all. The patient having been put under an anæsthetic, the skin should be cleansed and disinfected in the manner previously described, and if there is any earth or gross dirt still visible about the wound the tissues involved should be cut or clipped away and the raw surface daubed with liquid carbolic acid. Apart from this, which is only occasionally necessary, the important point is to provide the freest possible escape for discharge, and in order to obtain this it is often necessary to enlarge the original openings and to make counter openings. Further, any foreign bodies which are readily accessible, such as clothing or fragments of shell retained in the wound, should be removed, but at this stage it is not advisable to open up fresh wounds in the deeper tissues in order to hunt for bullets or pieces of shell, for this is only to expose fresh tissues to infection unnecessarily before the body generally has developed its full resisting power.

As to the actual drainage of the wounds, that must be carried out by the use of as large drainage tubes as can be conveniently introduced, with holes of suitable size cut in their sides; where there are counter openings it is well to pass the tube through from one opening to the other. A most extraordinary practice has grown up of late—viz., instead of using open tubes, to introduce masses of gauze into the wound under the idea that they will drain away the pus. Even those who use tubes generally slit them open at one side and fill them with gauze. Now the object of drainage and dependent openings in these cases is to let the pus run away as soon as possible so that the products of bacteria shall not lie in the part and cause local irritation or be absorbed. To push gauze into a sinus is effectually to prevent the pus escaping freely; and the pus soaking into the gauze and lying there undergoes still further changes as the result of the bacteric growth, and becomes a highly poisonous and irritating substance. Whoever heard of stuffing a drain-pipe with gauze so as to let water run away, far less thicker material like pus?

I cannot conceive how this method of draining wounds ever arose; I fancy it was some aseptic surgeon who found that when he put a drainage tube into a wound the wound always suppurated, and the bright idea occurred to him that by using gauze instead he would keep bacteria out. However it arose, I regard it as one of the most foolish and mischievous things that have ever been introduced in connexion with the treatment of wounds, and especially of suppurating ones.

I may illustrate this by an anecdote. Some years ago I built a house in the country and we had some difficulty in getting a proper water-supply. At length I found a spring on the top of a hill in the neighbourhood where the earth had been somewhat hollowed out and which was used by a crofter not only for household purposes but also to water the animals. I got leave from the landlord to make a proper well there and to get the overflow for my own use. This I did, making a nice clean well for the crofter with an overflow to water the animals, and this left ample water for my house. The crofters are very conservative people, though they always vote for the Radical candidate, and this particular old lady had a great affection for the old well and resented very much the new one. To relieve her feelings she put all sorts of things—rotten fish, &c.—into the well. We did not notice this at first, and thought the water was extra good and tasty, but presently the flow of water through our pipe began to fail and ultimately stopped altogether. On examining the well the spring was all right, and there was nothing for it but to dig up the pipe. About a hundred yards from the well I found a piece of dirty linen, evidently a portion of the old lady's chemise, which was very rotten and completely prevented the flow of water. Now this is exactly what you do when you fill a drainage-tube with gauze; you prevent the free exit of the pus, and the gauze becomes very rotten and poisonous.

I do not think one can go too far in preventing the accumulation of septic material in a wound. Two of the very best cases which I have so far had have been cases of fracture of the pelvis with extensive tearing of the rectum. For a few days they were treated by drainage, a large tube through the anus, constant irrigation, &c., without any improvement, but as soon as I performed colotomy and cut off the access of fæces their improvement was immediate and most remarkable, and one of them has already healed and will soon be in a condition to have his colotomy opening closed.

Dressings.—Irrigation.

As regards dressings in these cases, of course aseptic dressings are not only useless but injurious. The septic discharge soaks into them and decomposes there, and the dressing simply becomes a septic poultice which poisons the wound. Antiseptic dressings are rather better, and in small wounds do well enough, the dressings I use being cyanide gauze next the wound with salicylic wool outside. But in large wounds the pus does not take up enough antiseptic to stop the decomposition entirely, and I am not at all satisfied with large masses of dressings over a wound. I believe that in these bad septic cases the less dressing you apply the better, and my experience is that as regards dressings it is best in these cases only to lay a few layers of antiseptic gauze over the wound to prevent it being soiled by the clothing or blankets, and to apply boracic fomentations and change them frequently. To pile on dressings on septic wounds, whether these dressings do or do not contain antiseptic substances, is only to revert to the old methods of two or three centuries ago which have been long since, and quite rightly, discarded. Wherever it is possible, however, in the case of large wounds and those involving bones or joints, constant irrigation with normal saline solution is by far the best method of treatment where circumstances allow of the employment of this plan. The irrigation is at first continued day and night, but after some time, as the discharge gets less and the wound begins to heal, boracic fomentations may be substituted during the night, but the irrigation should be continued during the day till healing is nearly complete. Where gangrenous processes set in, a water bath, frequently changed, with a little iodine or permanganate of potash in the water is the best treatment.

Removal of Missiles.

There is just one other point to which I shall refer—viz., the question of the removal of the missile which has done the damage. Of course, if it is present in the main wound, or is doing harm by pressure or otherwise, it should be removed at once; but not uncommonly fragments of shell or bullets pass into the tissues for a considerable distance from the main wound, and if left alone may become encapsuled and not do any harm and the wound of entrance will heal quite well. Such fragments can be removed by a separate incision later if necessary. I think that there is too great a tendency to hunt for small fragments of shell or bullets at the present time. It is interesting that when they traverse the tissues for some distance they seem to shed the septic material which they have carried in with them. I have one case where a piece of shell passed through the rectum and is embedded deeply in the other thigh and is not causing any irritation. It is well, however, to have a stereoscopic skiagram taken in all these cases as soon as the condition of the patient allows; this will help the surgeon to determine later if he should remove the fragment.

CONCLUSION.

Gentlemen, I am afraid I have taken up far too much of your time, but the question I have been referring to is one of tremendous importance, and I entreat you to give it your most earnest consideration. If you have followed what I have said, it is clear that I only advocate the use of antiseptics at the very commencement of the treatment, but at that time, in order to serve the purpose, they must be sufficiently powerful. I am much opposed to their use in suppurating wounds. Some object to the use of these strong antiseptics on the ground that they may cause a slough. This, however, is a mistake; used as I have advised they may kill a microscopic layer of the surface of the wound, but they cause no visible slough. Even if they did cause a slough, if you have destroyed the bacteria the slough is of no consequence; it will be absorbed like any other piece of dead tissue, and what does a slough matter as compared with the life and future usefulness of the patient? It is very trying for those of us who are parents to feel that any day we may hear of the death of our boys in battle. If they die on the field of battle, they at least die nobly in fighting for their country and for the safety of those they have left behind. Surely it makes it still harder for us to know that if they escape death on the field of battle they may still, as the result of imperfect disinfection of the wounds, die from sepsis or be maimed for life. I beg of you to consider this matter calmly and logically and without prejudice, and see that every possible means is taken to avoid this great calamity.

SPLENOMEGALIC (HÆMOLYTIC) JAUNDICE ASSOCIATED WITH BILE PIGMENT IN THE URINE.

REPORT OF A CASE IN WHICH SPLENECTOMY WAS PERFORMED.

By T. R. C. WHIPHAM, M.A., M.D. Oxon., M.R.C.P. Lond.,

PHYSICIAN TO THE EVELINA HOSPITAL FOR CHILDREN; ASSISTANT PHYSICIAN AND PHYSICIAN IN CHARGE OF THE CHILDREN'S DEPARTMENT AT THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.

With Remarks by H. W. Carson, F.R.C.S. Eng., *Senior Surgeon, Prince of Wales's General Hospital.*

The term "acholuric jaundice" is the one which is usually employed to designate that class of case in which more or less persistent jaundice occurs in association with enlargement of the spleen and frequently with that of the liver also. The disease is now regarded as a clinical entity, but its nature requires further elucidation. The condition is most frequently congenital, but in some instances the onset apears not to commence until somewhat later in life. It is also familial in that more than one member of a family and successive generations may be affected. The syndrome comprises in addition to the jaundice and enlargement of the spleen and liver already referred to an anæmia, which is characterised by an increased fragility of the red corpuscles and a low colour index, together with coloured stools and urine containing urobilin but free from bilirubin. These characteristics of the urine have up to the present time been regarded as essential features of the disease, but I venture now to raise the question whether too much stress has not hitherto been laid upon the acholuria.

Such observers as Banti, Parkes Weber, and Poynton have noted the occurrence of bile pigment in the urine during exacerbations in cases of acholuric jaundice, and in Weber's case of persistent slight jaundice,[1] which will be referred to again later, Gmelin's reaction was frequently positive. It is also possible that bilirubin in small quantities may occur in the urine, although its presence cannot be detected. In such instances the characteristic reaction may be masked by other pigments which accompany it.

It thus appears that in some cases bile pigment is not uniformly absent from the urine. The case related below, however, affords a new aspect of the disease as regards the bilirubinuria in that the jaundice was always found to be accompanied by the presence of bile pigment in the urine and an absence of urobilin. The urine was examined on several occasions both before and after splenectomy, and at each examination this was found to be the case. It is, therefore, perhaps better to abandon the term "acholuric" as applied to these cases and to designate the disease as in the title to this paper from its chief symptoms—viz., jaundice, hæmolysis, and splenomegaly. Other names which have been given to the condition are also open to objection. Splenomegalic anæmia does not seem sufficiently distinctive, and further might be confounded with splenic anæmia. Hæmolytic splenomegaly conveys possibly the suggestion that the hæmolysis is due to the direct action of the enlarged spleen upon the blood, of which there is no certain evidence. The action of the spleen is probably by means of its internal secretion, which exerts an influence on the bone marrow tending to the production of red blood corpuscles deficient in their power of resisting hæmolysins; in this way the organ is indirectly the cause of the hæmolysis. The term "cholæmia," on the other hand, has the advantage of being short, but is somewhat indefinite. I would suggest, therefore, that the name "splenomegalic jaundice" (with perhaps the additional adjective "hæmolytic") be used for this disease, at all events until a clearer insight into its nature is obtained. It would at any rate avoid the confusion caused by the multiplicity of terms.

The case which I have to report is that of a girl, aged 6 years, who was born jaundiced. The icterus lasted for six weeks, but from that time until three months previously to being seen at the Prince of Wales's Hospital (May 26th, 1913) she was said to have been free and to have had good health. In February, 1913, there was a sudden recrudescence of the jaundice, and the child began to look anæmic and to lose flesh. Epistaxis occurred from time to time, but there were no other hæmorrhages. The stools were normally pigmented and the urine was of a deep colour. The patient was a well-grown girl who appeared somewhat anæmic and listless, but the most striking feature about her was a deep olive-green jaundice, the most intense that I have seen in a child. The spleen was enlarged, its lower pole being felt about halfway between the costal margin and the umbilicus, and the liver also was considerably increased in size. The stools were coloured, bile pigment was present in the urine, and a blood count showed a lymphocytosis. There was no history of a similar condition in the family or of syphilis, there being only an elder brother, who had always been healthy. The mother had had no miscarriages, and a month later gave birth to a healthy child with no signs of jaundice. The Wassermann reaction, moreover, was negative. Frequent attacks of epistaxis supervened, and at the end of a few weeks the jaundice was slightly less marked. The spleen, however, became more enlarged and extended nearly to the umbilical level; the liver edge also could be felt a little lower than at first. At the end of three months (September) the icterus was distinctly less and a slight rose colour could be seen in the cheeks. At the same time the urine was less pigmented with bile. The spleen was slightly larger, but the liver, which in July had reached below the level of the umbilicus in the right nipple line, had somewhat decreased in size. The motions, as at first, were always pigmented. The temperature when taken was slightly raised, varying between 99° and 99·8° F. Examinations of the blood showed a diminution in the number of red corpuscles, and in October they did not amount to half the original count. Some enlargement of the cervical and axillary lymphatic glands was now noticed, but the patient seemed to be holding her own in spite of the deterioration of the blood, and had gained $4\frac{1}{4}$ lb. in weight in less than four months. The jaundice by this time had still further diminished, but the urine continued to show the presence of bilirubin and was free from urobilin. The spleen continued to increase slowly in size, and by December it extended below the level of the umbilicus; the edge of the liver was then also lower again. The blood showed a further deterioration, and the fragility of the red corpuscles as tested with sodium chloride solutions was increased, hæmolysis occurring in a 0·55 per cent. solution of NaCl, but not in a 0·6 per cent. The patient continued to gain in weight, but a certain degree of jaundice persisted, and the general condition became more and more unsatisfactory in spite of treatment with arsenic, iron, and other tonics. By March, 1914, she had gained a further $4\frac{1}{2}$ lb. in weight, but the blood count had fallen to below 1,000,000 red cells per c.mm., and the fragility was still more marked than normal. The spleen at this time was slightly bigger, but the liver edge had again receded somewhat. I therefore asked my colleague, Mr. H. W. Carson, to see the patient, and he agreed to remove the spleen.

---

[1] Transactions of the Clinical Society of London, 1903, vol. xxxvi., p. 247. This case is a doubtful example of those under discussion, as no obvious alteration in the size of the liver or spleen could be made out. Dr. Weber informs me that the patient died nine months later in another hospital, but no necropsy was obtained.

On April 7th splenectomy was performed. The patient stood the operation well and at once began to improve. Her spirits rose, the jaundice disappeared, and a healthy colour soon returned to the cheeks. The temperature, which had been from 99° to 100° F., fell to normal by the end of a week, and in a fortnight a blood count showed an increase of over 3,000,000 red cells per c.mm., although the colour index was only slightly increased. The patient was sent to the convalescent home and returned in May to all appearance a healthy child, having regained the weight which she had lost as the result of the operation. A blood count, however, showed a diminution in the number of erythrocytes, but the colour index was higher. The liver remained the same size as in March. Subsequently the patient had some epistaxis, but continued in excellent health, and on July 13th the red cells had risen to 6,000,000 per c.mm. and showed a normal fragility. On July 24th, however, the patient was sick and out of sorts generally. Epistaxis occurred and the jaundice returned, the urine again becoming dark coloured. On the 27th she was peevish and not nearly so well. She had lost her colour and presented a degree of jaundice similar to that shown before her operation. She had also lost 4¾ lb. since her previous weighing on June 3rd. The tongue was coated and the temperature 99·4° The blood showed only a slight decrease in the number of erythrocytes, but a distinct fall in the colour index; the fragility of the red cells was normal. The urine was again found to contain bile pigment, but no urobilin. Three days later the patient died at home. No necropsy was performed.

On Oct. 16th, 1913, several normoblasts were present. Splenectomy was performed on April 7th, 1914. The difference in the readings of subsequent dates should be noted.

The production of the jaundice in some of these cases is probably not entirely the result of blood destruction. In the case just related the very deep jaundice at the commencement was not associated with any marked decrease in the number of erythrocytes; indeed, they were at the time only just below 5,000,000 per c.mm., and it is to be remarked that the jaundice lessened coincidently with the diminution in the number of red cells. It would seem, therefore, that the jaundice is in some measure due to changes in the liver, but whether this occurs as a complication or as an essential part of the syndrome must for the present be left undecided. The fact that the liver in these cases is usually enlarged points to the presence of some coexisting abnormality in that organ, but the nature of the pathological changes which occur has not been accurately determined, though it has been noted in those instances in which the liver has been examined post mortem that no cirrhosis has been found. A participating factor in the production of the jaundice might thus be a cholangitis causing sufficient obstruction for a portion of the bile to find its way into the lymphatics and subsequently to appear in the urine, but not severe enough to prevent the escape of bile into the duodenum, thus allowing the stools to be coloured. It is possible that some degree of cholangitis exists in all these cases, and that the occasional presence of bilirubin in the urine is due to an increase of that condition. In the case related above it may be supposed that the initial deep jaundice was caused by a somewhat severe cholangitis which brought about an increase in the icteric tint produced by hæmolysis. With the diminution of the cholangitis the jaundice lessened, though a certain amount remained. After the operation, which appears to have exerted a temporary beneficial effect on the liver, a return of the cholangitis occurred, giving rise to further jaundice and possibly a toxæmia which resulted in the death of the patient.

A fatal termination to the case was very disappointing after the immediate brilliant effects of the splenectomy, and it is to be regretted that no necropsy was held to determine the condition of the smaller bile ducts. In this connexion it may be remarked that two cases of hæmolytic jaundice reported by Dawson[2] were associated with affections of the gall-bladder, one with gall stones and the other with cholecystitis; both of these at one time had bilirubinuria, but it was not constant. Banti also states[3] that when the anæmia is intense a small quantity of bilirubin may be present, and has reported one or two cases in which this was so, though it would now seem open to doubt whether the bile pigment was really due to an increase in the anæmia and not to an inflammatory condition of the smaller bile-ducts. The same author further remarks that under the same conditions a few myelocytes may be found in the blood. This was exemplified in my case.

So far as I am aware no case has hitherto been reported in which the presence of bilirubin and an absence of urobilin in the urine were persistent accompaniments of splenomegalic jaundice. The only one which I have found at all resembling it is Weber's case of persistent slight jaundice[4] already referred to, but in that case urobilin was definitely present on at least one occasion. Moreover, no enlargement of the spleen or liver could be detected, and for this reason it is doubtful whether it should be included in the same category.

[2] Proceedings of the Royal Society of Medicine, 1914, Clinical Section, pp. 101, 103.

[3] La Semaine Médicale, 1912, vol. xxxii., p. 265.

The cause of the splenomegaly in these cases is unknown, but the influence exerted by the perverted internal secretion of the organ on the hæmolytic resistance of the erythrocytes is shown in the case here recorded. After splenectomy had been performed the red cells not only increased in number to a remarkable extent, but also regained their normal fragility, while the colour index showed a gradual improvement. Several observers, however, have found that there has been very little or no improvement in the fragility after the removal of the spleen, but observations, as a rule, have only been recorded for a brief period after operation. In a few cases, on the other hand, as in my own, the fragility has been diminished, but in some instances an improvement has not been noticed until some time after the operation.

A record of the subsequent histories of all these cases in which splenectomy is performed is very desirable. The operation, so far, has been fully justified by its results. Thursfield and Gow[5] have collected ten cases, with an additional two in which the diagnosis was doubtful. In all of these except one, in which death occurred from sepsis of the pedicle, the operation was followed by good results, and Banti even goes so far as to say that "in that group of hæmolytic jaundice in which splenomegaly represents the primitive and principal lesion surgical treatment succeeds in curing rapidly and radically that jaundice which treated in another way would certainly have a fatal issue."

Remarks by MR. H. W. CARSON.

The removal of the spleen in these cases is rarely a difficult operation. The spleen is large, firm, and generally fairly free from adhesions. There are three main rules, common, it is true, to all abdominal operations, which must be emphasised in the operation of splenectomy—namely, free exposure, delicate handling, and careful hæmostasis. Most of the difficulties can be avoided by making a free incision. This should be a vertical incision through the upper part of the left rectus, much the same as the incision for cholecystectomy on the right side. It should vary in length according to the size of the spleen, but will generally extend from the costal margin to the level of the umbilicus. After opening the abdomen, the presence of adhesions must be ascertained, and before anything else is attempted all adhesions must be cleared, not by breaking down, but by clean division after clamping. If the adhesions are broken down roughly, there may be a considerable amount of hæmorrhage the control of which may prolong the operation unduly. The spleen, freed from adhesions, is then lifted out of the abdomen and the pedicle tied. Occasionally the veins of the pedicle are very thin-walled, and care must be taken in lifting the spleen out of the abdomen that no strain is thrown on them. The pedicle is tied off with interlocking ligatures of thick catgut, reinforced by an additional ligature including the whole stump, and the spleen cut away. A careful examination of the cavity from which the spleen has been removed, including the under surface of the diaphragm, methodically done under a good light to detect the slightest hæmorrhage, completes the operation, and the abdomen is closed without drainage. The immediate result of the operation for the disease under consideration is, in the few cases recorded, very good. The dangers of the operation, shock, sepsis, and hæmorrhages, are all preventable, and this patient seemed to feel the operation very little. Whatever the exact physiological effects may be of removal of the spleen, clinically the improvement in this case was surprising. A fortnight after operation the child had lost her jaundice, and instead of being depressed and listless she had a good colour and seemed bright and active. The improvement was only temporary unfortunately, but immediately the operation had a very profound effect.

PITYRIASIS ROSEA OF GIBERT.

BY E. GRAHAM LITTLE, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT AT ST. MARY'S HOSPITAL, PADDINGTON, AND AT THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

INSTANCES of a recurrence of the eruption of pityriasis rosea are so rare as to be worthy of record. In a survey of the literature of the disease, which was necessitated by the preparation of a paper read by me before the Dermatological Section of the Royal Society of Medicine in February last, I collected at the most six instances of recurrence, some of which were of doubtful authenticity.[1] The best observed and most precise of these was contributed by Szaboky[2] from Professor Nekam's clinic in Budapest, and as it offers a curious similarity to the case I am about to record I give his description in some detail as follows.

The patient, a male aged 19 years, was seen on Feb. 15th, 1899, when he had an eruption of pityriasis rosea distributed on the upper extremities, the sides and the nape of the neck. The eruption was slightly itchy, and disappeared under treatment within six weeks. Sweating was a prominent feature. In the beginning of April—that is, a few days after the complete removal of the first eruption—recurrence of a similar rash in the same positions as in the previous attack was noted. Sweating, which had diminished after the cure of the first eruption, increased during the new outbreak, which was cured in five weeks. Search for ringworm organisms proved negative. Cultures gave only sarcinæ and bacteria. Inoculations of scales into human beings gave no result.

In addition to this observation, which is the only one I have come across which has been recorded with any degree of precision, there is a very incomplete note by Allen[3] in the course of a discussion on pityriasis rosea, in which he observed that he had seen a patient who had had at least seven attacks, coinciding with periods of abstinence from alcohol, such abstinence appearing to cause disturbance of his digestive functions. These periods seemed to date from New Year resolutions of sobriety, imperfectly kept. Phillips[4] has a note of a curious case which seems to be rather an instance of abnormal persistence of eruption than of recurrence, since no mention is made of intervals of freedom. The record is essentially as follows. When first seen, nine months previously, there had been circinate patches involving trunk, thighs, and arms. These had faded characteristically but had left irregular-shaped patches of eruption symmetrically placed at the sides of the neck, anterior and posterior folds of the axillæ, and over the prominences of the hips. The efflorescence was indolent, rose-brown in colour, dry, finely desquamative, and slightly raised above the surface of the skin, especially at the margins of the patches. Twice during the time that he was under observation the patient had had jaundice. Sherwell[5] makes a casual reference to a case in which he had noted recurrence of an eruption of pityriasis rosea during repeated pregnancies, but the record is too meagre to afford any information of value.

---

[2] Szaboky: Monatshefte für Praktische Dermatologie, 1906, vol. xlii., p. 495.

[3] Allen: Journal of Cutaneous Diseases, New York, 1896, vol. xiv., p. 356.

[4] Phillips: Brit. Med. Jour., 1895, vol. i., p. 254.

I now give the details of the case which prompts this note and which is the first instance of recurrence to come under my own notice. In my paper of February I tabulated 174 personal observations of the disease occurring in some 27,000 cases of general skin disease, and in none of these was recurrence observable.

The patient, a boy, aged 5½ years, was brought to see me at St. Mary's Hospital skin department on July 9th, 1914, by his mother. He showed a very typical and definite eruption of pityriasis rosea, distributed in the usual positions on the back and sides of the trunk. The mother said the eruption had begun a week previously with several patches which had preceded the general eruption by a few days, and which could be still identified as being larger, and therefore presumably older, than the rest of the rash. There was much itching, but no other affection of the skin except that there were a few small scars of a recent varicella and three much larger and older scars from a burn sustained in earlier childhood. Scales were examined for fungus with negative result, the diagnosis of "pityriasis rosea with several pioneer patches" was unhesitatingly recorded, and the patient was given a mixture of salicin and potassium citrate and no local remedy ordered. He was seen again by me on July 16th, when a saline aperient was added to his treatment, as he complained of constipation; the rash was unaltered at the second visit. Owing to the absence from London of the mother and the boy the patient was not again seen by me until Oct. 8th, but the history of events in the interval was very clearly given by the mother, who displays exceptional intelligence. She states that she was confined of her second child on July 30th—an event which explains the particularity of her recollection that a few days prior to that date the patient was sent to his paternal grandmother, living at Yarmouth; that before he left she, the mother, noted the state of the boy's skin carefully, as she was afraid the grandmother might have objections to receiving the child, and that when he was actually sent there were only faintly scaly marks with no remaining pinkness of tint which had particularly attracted her attention in the observation of the initial eruption. The grandmother, whose adverse reception of the child had been feared, made no comments, and the boy was returned to his mother's charge on August 10th, but was not critically inspected by her until about August 21st, when she specially noted that his body was perfectly clear of any trace of eruption. In the interval between the 10th and the 21st the boy had been bathed and looked after by his maternal grandmother, who failed also to note the presence of eruption. From August 21st to Sept. 20th the child was regularly bathed by his mother, and no eruption was seen until about the latter date, when a new eruption, exactly like the previous one, was noted on the back and front of the trunk, which took about four days to reach its full development, and was characterised by the same pink colour on which the mother had before laid stress. He was brought to me again, as I have mentioned, on Oct. 8th. On this date I noted a copious attack of typical pityriasis rosea, occupying the front and back of the body, with all the characteristics of the disease corresponding to the duration of the eruption (about 14 days) as given by the mother. There was not any itching with the second attack, but with this exception it was exactly similar to the earlier rash. Scales were again examined for fungus with a negative result, and he was again given a mixture of salicin and potassium citrate, without any local application. He was brought to me for examination on Oct. 12th and Oct. 19th, when the eruption was noted as progressively fainter in colour, and it had completely disappeared by Oct. 26th. He has remained clear up to the present date (Nov. 12th), when he has been discharged from attendance.

There is thus good evidence for stating that the first eruption persisted for five weeks, was followed by an interval of complete freedom of somewhat over a month, and that a second acute attack of the disease with characteristic inauguration and evolution of the eruption persisted for nearly five weeks, when it also disappeared under purely expectant treatment.

Wimpole-street, W.

TRAUMATIC RUPTURE OF THE LIVER; LAPAROTOMY; RECOVERY.

By LEONARD H. TAYLOR, M.B., B.S. LOND.,
MEDICAL OFFICER TO THE KELANTAN GOVERNMENT, PROTECTED MALAY STATES.

CASES of rupture of the liver being uncommon, and the instances of recovery being still more so, I think it may be of interest to publish the notes of this case which came under observation in the Government Hospital, Kelantan.

On June 13th, at 10 A.M., a Tamil woman was admitted with the following history. At 9 o'clock on the preceding morning her husband had returned home drunk, and after bullying her for some time had pushed her through the window of their house into a drain four feet below. He then walked round and jumped on her many times, stamping on her chest and abdomen. Without assistance she was unable to leave the house that day, but in the evening her friends took her to make a report at the police station, and the next morning the officer in charge brought her across river in a native boat and to hospital in a rickisha. On arrival she was seen by the residency surgeon and myself, and the following signs and symptoms were noted. There were no external bruises or cuts. On inspection the abdomen was found to move fairly well; there was, however, marked distension below the umbilicus. On palpation the upper part proved tender, especially over the right kidney. On percussion there was dulness in the flanks, more marked on the right side, and the distension noted above was resonant. The patient's general state was poor, the pulse being weak and rapid, but there was no rise of temperature.

---

[5] Sherwell: Journal of Cutaneous Diseases, New York, 1896, vol. xiv., p. 355.

At midday an exploratory laparotomy was made, and the upper part of the abdomen was found to be full of dark blood, which issued in large quantities. On passing the hand in and round over the surface of the liver a tear was found about $1\frac{1}{2}$ to 2 inches in length by $\frac{1}{4}$ inch in depth on the outer surface of the right lobe. The residency surgeon after examination decided that nothing could be done since the wound was out of reach except to the hand, and the patient's state on the table was extremely critical. The abdominal incision was therefore closed up with three interrupted silkworm gut sutures through the peritoneum and all the layers. The patient was then moved back to bed as quickly as possible.

The after-treatment was practically *nil*, for on the day of the operation cholera broke out in the gaol and the hospital patients could only get very scant attention. The dresser, however, reported each day that the patient did not improve and that her pulse could hardly be felt, but on the fifth day I visited the ward and found her sitting up on her bed. From then onwards she improved daily, and 13 days after the operation she left the hospital, refusing to stay any longer.

The wound in the liver might have been packed with gauze to inhibit bleeding, but it was thought that binder pressure over the ribs would bring about the same result, and this seems to have been the case.

Kelantan, P.M.S.

MORPHOLOGICAL TYPES OF BACILLI AS AN ELEMENT IN PROGNOSIS IN PULMONARY TUBERCULOSIS.

By HORACE R. WILSON, M.D., B.S. Lond.,
M.R.C.S. Eng., L.R.C.P. Lond.,
TUBERCULOSIS PHYSICIAN TO THE SOUTHWARK BOROUGH COUNCIL;
LATE TUBERCULOSIS PHYSICIAN TO THE WELSH
NATIONAL MEMORIAL.

During the examination of samples of sputa from cases of varying type there is marked difference in the appearances shown by the acid-fast bacilli, though the greatest care has been taken to render the processes as identical as possible. In one case the bacilli are short, plump, and taking a uniform stain, with a noticeable absence of the clear spaces so frequently seen and which were once considered spores; in another specimen the bacilli are longer and thinner, the clear spaces numerous and well marked, the stain less deeply taken, and, excepting the acid-resisting properties common to the two, quite distinguishable from the first type. Again, we frequently meet with cases midway between the two. Spengler at one time attributed these differences to the human or bovine origin and considered the staining of the waxy envelope responsible for the difference in appearance of the strains of bacillus, but this explanation is not accepted by other authorities, nor is it substantiated by more recent investigation, for the report of the recent Royal Commission on Tuberculosis concludes that the microscopical appearances alone are insufficient to differentiate between the different types of bacillus. Muir and Ritchie in their "Manual of Bacteriology" on this point hold the view that there are the two different strains of organisms which on cultivation resemble in appearance the two types as described by Spengler and mentioned above, which vary in virulence and cultural characteristics. On the other hand is the view that the beaded type is a degenerate strain of that which stains homogeneously, and this view also finds able supporters.

At the International Congress in Brussels in 1910 the following results of experiment were recorded by Maher, of New Haven (Connecticut): "New growths of any strain—avian, human, or bovine—are consistently acid-fast and stain entire, and are of uniform size when grown on glycerine broth, glycerine agar, or glycerine potato broth. Old growths on glycerine broth grow long and filamentous, beaded and granular, say at six months, and partly lost their resistance to acids." In the same connexion Muir and Ritchie state: "We can only say that the younger bacilli stain uniformly and that in older forms inequality in staining is met with. This latter condition is, however, not found to be associated with greater powers of resistance." These observers, however, uphold the optical differences mentioned above as characteristic of the human and bovine bacilli respectively, but add that intermediate forms are met with, and that "in view of these facts it is probable that bovine bacilli will undergo corresponding modifications in tissues of the human subject."

Whether these differences in appearance are due to the fact that the one form is bovine, the other human (Spengler), or that they are respectively the young or old type of bacillus of either strain (Maher), which view is also favoured by myself, the difference has a distinct bearing on the prognosis of the case, and in examining sputum from a tuberculous case it is insufficient to detect the mere presence or absence of bacilli, but their morphological characteristics should be noted as to size, vacuolation, and acid-resisting properties. Variations in appearance of the bacilli coincide as a rule with the virulence of the attacking force, acuter and more florid cases harbouring bacilli corresponding to the young growths and the more chronic cases with fibrosis and old cavities being the hosts of the moniliform type. Either type (whether looked on as "old and young" or "human and bovine") may be conveyed to the lung by inhalation and may be the starting point of infection, and we may take as a prognostic axiom the "younger" the type the more virulent the case.

If certain cases are watched over a long period and the sputum systematically examined the type of bacillus is found steadily to approximate the vacuolated type, and two explanations may be suggested for this. The one explanation is that the bacillus is originally of bovine strain, but under the influence of environment it is gradually adapting itself to human surroundings and at the same time decreasing in virulence; or, secondly, that the original strain, whatever its origin, is losing ground against strong resistance, which view is more in accordance with present opinions cited above.

This leads to another aspect of the question—namely, whether the changes are due primarily to bacillary alteration or to varying resistance in the tissues of the individual infected, the resistance being either acquired or inherited, or to both. A consideration of this aspect gives us four possibilities: (1) a virulent strain of bacillus and poor resistance; (2) a virulent strain of bacillus with good resistance; (3) a feeble strain of bacillus with poor resistance; and (4) a feeble strain of bacillus with good resistance. Whereas (1) leads to an acute rapid case of "galloping consumption" the course of (4) may probably lead to a permanent arrest before much damage is done to the tissues; (2) may lead to degeneration of the tissues and ultimate chronicity, a dangerous type of case from the preventive point of view, and (3) to a slowly smouldering progressive case, probably non-febrile but nevertheless going steadily downhill.

It follows that a knowledge of one's patient and careful inspection of the characters of the bacillus may be of considerable assistance in prognosing the course of a case, and as a result evidence as to the best method of treatment to advise the patient to pursue. Resistance is the predominant factor in influencing prognosis, and all efforts should be aimed at the production of high resisting power, as this is the factor under our control. Given good resistance, fortified by suitable treatment, and the type of bacillus will be found to deteriorate as stated above, while nature erects barriers of connective tissue to the progressive course of the disease, gains time for antibody formation which still further causes degeneration of bacilli, and by contraction of fibrous tissue lessens cavities and controls blood supply, although in rapidly fatal cases the end has arrived before the defensive mechanism has accomplished its work.

What is the ultimate fate of the degenerate bacilli in cases which successfully progress to chronicity? There is no doubt they ultimately disintegrate and that the portions retaining the stain have a dormant existence, and either under the synonyms of Much's granules or Spengler's "splitter" forms can recover vitality under suitable conditions of soil and temperature and become responsible for many cases of relapse or infection. These granular forms should be specially stained for either by Much's modified Gram method or by Spengler's "pikrin" method. Should they be present they are of great importance as proving the patient a carrier of tuberculosis and a public danger. From the prognostic point of view they are of good omen as showing high resisting powers.

In conclusion, I wish to point out that the microscopical type of bacillus considered periodically in conjunction with the general and local condition of the patient is of great assistance in prognosis, and also that the sputum of cases of chronic tuberculosis, asthma, bronchiectasis, and bronchitis should be specially examined for sporadic forms of bacilli, which, with a little extra care, may be recognised by appropriate staining methods, and which are a source of great danger to the public health and a frequently unrecognised focus of fresh infection.

King James-street, S.E.

ISOLATION HOSPITAL FOR SOUTH DEVON.—The Local Government Board recently suggested that a joint isolation hospital should be provided for Dartmouth, Totnes, Kingsbridge, and Salcombe, and a meeting was held at the Dartmouth Guildhall last week to consider the scheme. After some discussion a resolution was passed in favour of the proposal. It was also decided to ask the Local Government Board to send a representative to discuss the whole question, and to consider the advisability of appointing a whole-time medical officer of health for the joint district.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF LARYNGOLOGY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 6th, Dr. G. WILLIAM HILL, the President, being in the chair.

Mr. HERBERT TILLEY exhibited microscopic specimens from five cases of Aspergillosis of the Maxillary Antrum seen by him during the past ten years. All the patients were females, and the chief symptoms were sneezing, marked nasal obstruction, severe pain in the cheek, sometimes causing insomnia, slight purulent nasal discharge, and great œdema and opacity on transillumination. There had been difficulty in irrigating the sinuses because the material was semi-solid and of sticky consistency. He had experienced no difficulty in curing the cases by operations, and there had been no tendency to recurrence.—Mr. S. G. SHATTOCK remarked that at first he believed that the disease was a mucinoid endothelioma such as may be found in the abdominal cavity, but that later it seemed probable that it was caused by a mycelium differing from that of thrush, sporothrix, &c. No cultivations of the secretion had been made.—Mr. W. DOUGLAS HARMER referred to a similar case which he had reported in the Transactions which was proved by cultivations to have been caused by aspergillus fumigatus. In that case there had been great difficulty in curing the symptoms, and the most effective remedy seemed to be sodium iodide in large doses.—The PRESIDENT pointed out that iodides are often successful in curing actinomycosis.—Dr. D. R. PATERSON had seen aspergillus infections of the lacrymal sac, and thought that they might be grafted upon old suppuration.—In this connexion Mr. SHATTOCK pointed out that the lung may become secondarily infected with aspergillosis.

The PRESIDENT showed skiagrams of Frontal Sinuses operated on by Good's method. Watson-Williams's metal sounds were seen *in situ*. Good's bone files or rasps were exhibited. He remarked that this method was certainly capable of relieving troublesome symptoms and that the presence of fronto-ethmoidal cells was no contra-indication.—Dr. P. WATSON-WILLIAMS thought that one could not be too enthusiastic about the results obtained by Good's method, even if a free opening could be made. He referred to the possibility of making a perforation through the partition into the frontal sinus on the opposite side in cases where there was a large frontal cell on both sides.—Dr. DUNDAS GRANT considered that the rasp was extremely useful for endonasal treatment of the frontal sinus. He was glad to see that this method was becoming more popular.—Mr. TILLEY thought that a careful record should be kept of the cases in which a perforation had been made. He also referred to the cases where lotion syringed into one frontal cavity returned through the opposite side of the nose.

Dr. IRWIN MOORE showed a case of Abnormal Overgrowth of Nose (bulbous) in a child aged 9. He stated that the child was born with the condition simulating rhinophyma. On cutting into it it was found to consist of fine fibrous tissue with no definite capsule and adherent to the skin and cartilages. Treatment by diathermy was advised.

Dr. MOORE also showed a private patient of Sir StClair Thomson, a case of Stricture of the Œsophagus illustrating the benefits of Hill's tube. He stated that the patient had worn the tube for eight weeks, during which time he had become able to swallow liquids with little discomfort, was relieved of mucous secretion, had gained weight, was much more comfortable, and able to do his daily work.—The PRESIDENT pointed out that his tube was not so well tolerated in cases suffering from cancer of the cricoid region.

Dr. J. COUBRO POTTER exhibited sections from a case which had been referred for opinion by the section. The findings showed it to be a case of perithelioma of the nasopharynx.

Dr. DAN MCKENZIE showed a patient who developed an Abscess of the Frontal Lobe of the Brain, secondary to old-standing frontal sinus suppuration. The abscess was drained through the frontal cavity, and the patient made a good recovery.—Mr. C. A. B. HORSFORD drew attention to the difficulty of making a diagnosis of an abscess in the frontal lobe. In many cases the pus found was extradural.—Dr. P. G. **GOLDSMITH** stated that a frontal abscess might give rise to no symptoms whatever.—Sir **ST CLAIR THOMSON** described a case in which the abscess in the brain was on the opposite side to the sinus.

Sir **ST CLAIR THOMSON** showed a patient, aged 69, whom he thought to be suffering from Early Epithelioma with free movement of the cord. He had suffered from hoarseness for six months. The whole of the left cord was replaced by a red, knobby, ulcerating infiltration. The cords moved well. The rest of the larynx was normal. No enlarged glands. Wassermann reaction negative. No evidence of tuberculosis. He proposed to treat the case by laryngo-fissure.—Sir **FELIX SEMON** thought that it might be some obscure infection, or even tuberculosis.

Mr. G. J. F. **ELPHICK** exhibited a Hæmostatic Guillotine with which he had found it possible completely to enucleate the tonsils with very little loss of blood.[1] It was based on Sluder's method, and had one cutting and one crushing blade which entered between the anterior faucial pillar and the tonsil. On being pushed home this blade remained locked. The protruding tonsil being caught with a light fixation forceps the cutting blade was pushed home between the tonsil and the crushing blade, and the tonsil was lifted out with the fixation forceps. The crushing blade might be left a few moments compressing the cut vessels.

Mr. H. **LAMBERT LACK** showed a patient whom he had treated for extensive Papilloma of the Trachea, and Dr. **GRANT** and the **PRESIDENT** said that they had seen similar cases.

Mr. **HUNTER TOD** showed two cases of Epithelioma of the Tonsil to illustrate the results obtained by diathermy.—The **PRESIDENT** and Mr. **HARMER** expressed the opinion that diathermy was preferable to the knife in all such cases With the former method excellent results could be obtained, and the dangers of operation had disappeared.

MEDICAL SOCIETY OF LONDON.

Discussion on Surgical Experiences of the Present War.

A **MEETING** of this society was held on Nov. 16th, Sir **JOHN BLAND-SUTTON**, the President, being in the chair.

Sir **WATSON CHEYNE** opened a discussion on Surgical Experiences of the Present War. His address is published in full on p. 1185.

Sir **ALFRED KEOGH**, Director-General A.M.S., said he was glad that the subject was being discussed, for any conclusions arrived at would influence the methods of treatment adopted. He was particularly desirous of hearing opinions as to the value of the prophylactic doses of antitetanic serum, and concerning the treatment of wounds from the beginning, and also when they were dealt with under hospital conditions.

Sir **RICKMAN GODLEE** said that he agreed with every word of Sir Watson Cheyne's address. Before long, he thought, someone would rediscover the principles on which Lord Lister had worked. He would like to know what attempts were being made to disinfect wounds as soon as the patients were admitted to the field hospitals. By way of emphasis, he said that Lord Lister had often remarked that if he ever wrote a book—which he never did—the motto would be the words of the Psalm, "My wounds stink and are corrupt because of my foolishness."

Mr. **ARTHUR EDMUNDS** said that it was of course difficult at this stage of the war to generalise from a limited experience, especially as the cases which reached England were to a certain extent selected, the most severe and the most trivial remaining on the other side of the Channel, either because they could not be moved or because they were able to return to duty within a few days. Probably the cases seen in England could be fairly taken as those of medium severity. A great deal was being written about the *morale* of the navy and army. Certainly there was no place where this was more apparent than in the naval and military hospitals of this country; indeed, the extreme fortitude with which the most serious injuries were borne sometimes deceived the surgeon as to their extent. For example, a patient under his care was admitted with a swollen arm and a penetrating wound in the region of the elbow-joint. He complained of no pain, and accordingly was not put among the first batch to be sent down to the overworked radiographer. In due course a radiogram was obtained which showed extreme comminution of the bones entering into the joint. Neuroses were, however, met with, but in these cases the shock or strain had always been of the very severest character, at any rate in the cases which had come under his own personal observation. For example, a marine during the Antwerp expedition was overwhelmed by the collapse of a trench in which he was placed at Lierre. Several shells burst near him, one of which blew a comrade standing close to him to pieces. The patient regained consciousness two days later, but was completely deaf and dumb. He was at first thought to be mentally affected. His ears were full of wax, and Mr. Edmunds therefore took him into the aural department of the hospital so that he might remove the wax and examine his drums. During the process of syringing his ears a few bubbles of air entered the meatus and he obviously heard them. In a few moments with the aid of a little suggestion he could hear perfectly. Mr. Edmunds now attempted to make him utter a sound; this he did with difficulty, but was able shortly afterwards to make simple vowel sounds. He then suddenly asked him his name, and he answered clearly and correctly, exclaiming, "I can speak." He returned to duty two or three days afterwards perfectly well. Another marine, an officer, as the result of mental strain and sleeplessness, suffered from diplopia, but this also disappeared after a few days' rest. Another patient who had been shot through the angle of the lower jaw, the bullet lacerating the muscles at the base of the tongue, also complained that he was dumb, and made known his wants by writing them down. He wrote: "I cannot speak or swallow and my mouth is full of dirt." He was given something to drink and told he could speak. He reacted to the suggestion and had been able to speak, although with some difficulty, ever since. Mr. Edmunds was inclined to consider that the strain was more severe in the case of the navy, although he had no statistics to support this; the waiting to fight, and the ever-present danger from mines and submarines being more trying than the hardships of an active campaign on land. As regards actual wounds the present war had not yielded great surprises. It was, however, interesting to compare the wounds caused by the small fragments of shell which they saw at Chatham with the wounds from rifle and shrapnel fire which they had seen at Plymouth. Apparently the shells used by the enemy in the battle of the Heligoland Bight broke into small fragments which inflicted wounds very much like ordinary bullet wounds. A peculiarity of the German rifle bullet was the facility with which it turned right over; for example, he removed a bullet from a man's buttock which had entered over the sacrum about six inches away. The bullet was lying just beneath the skin with its point turned towards the wound of entry. In this case there was no great laceration of tissues, the wound consisting simply of a bullet track, and he was inclined to think that the bullet had completely turned round before striking, the trivial nature of the injury proving that the bullet was nearly spent. In the simpler wounds the bullet seemed to have passed directly through the tissues, making a small wound of entry and a slightly larger wound of exit, lacerating the intervening tissues very little. This was in marked contrast to the wounds which they saw as the result of the Heligoland fight, inasmuch as in the latter several cases had small wounds of entrance and exit but considerable laceration of the muscles. The probable explanation was that the more trivial bullet wounds were caused by a projectile rotating simply about its long axis, whereas in the naval action the wounds were caused by a fragment of shell moving with considerably less velocity but rotating rapidly around a transverse axis, forming a sort of flying circular saw. The importance of this was that a simple penetrating bullet wound of the soft tissues usually healed extremely readily, almost without suppuration, and beyond disinfection of the skin and the application of a dressing to the wounds of entrance and exit no treatment was necessary. In shell wounds, on the other hand, there was usually a deep cavity containing blood and lacerated tissue which was pretty certain to suppurate, and therefore such wounds should be explored under an anæsthetic and a good-sized drainage-tube inserted. The severer wounds caused by rifle bullets were possibly also to be explained on the theory of the rotation of a bullet about a transverse axis; some of these were superficial gashes which looked as if the skin had been struck by the side of the bullet; in others the extensive wound was probably produced by the high velocity of the projectile; thus in one case a man had a small wound of entrance on the back of the forearm and a wound of exit on the front of the forearm which was a deep chasm of about 4 in. by 2 in., the skin being split as if cut with a knife. He had seen one case in which this almost explosive action of the bullet was well exemplified, the patient being shot through the head of the tibia at about 100 yards range. It might be expected that the soft bone in this situation would be merely penetrated by the bullet, but as a matter of fact it was intensely comminuted, the interior of the bone feeling like a mass of sharp pebbles. In this case he was compelled to amputate the leg on account of the septic condition of the wound and the serious constitutional disturbance. The joint was uninjured, and he believed it might have been possible to save the limb had the patient been in better condition, but he had lain on the field for four days, having nothing to eat but mangel-wurzels, and nothing to quench his thirst but the dew which he could suck off the leaves. He had a small wound on the other leg from which Mr. Edmunds removed a fragment of leaf. He said that this patient's condition was exceptional, the bulk of the men being in excellent condition, and some of them having been wounded only 48 hours previously. As regards treatment in base hospitals in this country the essential point seemed to be to provide free drainage except in the cases which he had already referred to of simple petetrating rifle wounds; every case of a more severe nature had been complicated by a considerable amount of suppuration and sloughing. It would be unfair for those who were working in well-equipped hospitals in England to criticise those who were working at high pressure and often actually under fire abroad, but he would suggest that a more vigorous disinfection of recent wounds might ameliorate a good deal of this sepsis, and he believed that the use of pure carbolic acid should be more frequently adopted. He had had under his immediate notice two cases of extensive wound of the foot, involving the metatarsal bones of the great toe and the adjacent toes. The first of these he opened up, cleared out some loose fragments of bone, sponged the whole wound out with pure carbolic acid, and after putting in one or two drainage-tubes applied a dressing of cyanide gauze wrung out in 1 in 4000 perchloride of mercury. This wound was so severe that he was at first inclined to perform a partial amputation of the foot, and only refrained from doing so as the patient had already had the other leg amputated. This man healed up with healthy granulation, with no exfoliation of bone, and had already got a useful foot. In the other case the patient came under his care at a somewhat later date, but had been dressed within an hour of receiving his injury. The condition of his wound was approximately the same. Mr. Edmunds had treated him by a continuous bath and fomentations, the bath consisting of a tincture of iodine, 1 drachm to the pint. In spite of this there was some spread of the suppuration, the edges of the wound sloughed, and there were several of the pieces of bare bone exposed which must come away before the wound could heal. The difference between the progress of the two cases had been very striking, and was due, he believed, to the more vigorous disinfection which the first man received. The dangers of pure carbolic acid had been, he believed, exaggerated. It must, of course, be applied with discretion and not allowed to run over the skin; its application was for the moment painful, but not more so than tincture of iodine, and in any case it was usually necessary to give an anæsthetic in order to cleanse these cases efficiently. He believed that if in those cases in which there was a lacerated wound, especially one involving bone, it was possible to administer an anæsthetic and scrub the limb thoroughly with soap and 1 in 20 carbolic, cutting and cleaning the nails in wounds of the hand or foot, and then sponging the wound out with pure carbolic acid, very satisfactory results could be obtained. Anæsthetics were, of course, frequently out of the question, and therefore such methods of treatment were not practicable, but he believed that, wherever possible, this thorough disinfection should be carried out. Its utility after two or three days was doubtful, and in these cases it was probably wiser to trust to free drainage and antiseptic dressings, baths, and constant irrigation. In comminuted wounds of joints, where the joint was practically a bag of bones, an excision of the joint might be necessary to provide proper drainage. Another point in treatment was that of the advisability of removing bullets. These could be readily located by the X rays, and their removal did not, as a rule, present any very great difficulty. Shrapnel bullets were perhaps more difficult to find than rifle bullets, especially when they were embedded in muscle; not infrequently the bullet was found to lie in a small bag of pus, even when the wound of entry was completely healed, but very often the wound remained aseptic. In one case a man was shot in the shoulder through the deltoid, the bullet penetrating the thorax, wounding the lung, and coming to rest upon the diaphragm. There were pneumothorax and surgical emphysema over the pectoral and scapular regions, yet in spite of this the man had no symptoms and the bullet was allowed to remain. The possibility of deep suppuration was a reason for removing bullets wherever they were readily accessible; this should never be attempted unless the situation of the bullet could be determined by X ray localisation or other means. The telephone probe was a simple instrument and deserved to be extensively used, especially in the case of shell wounds, in which it was very difficult to distinguish a fragment of shell from the sharp end of a bone. In cases of difficulty—for example, when the bullet was embedded among the muscles of the thigh or buttock—it was a valuable plan to perform the operation upon the X ray couch. An incision was made over the approximate site of the bullet, through the deep fascia; a pair of Spencer Wells forceps was then thrust into the wound, a sterilised towel thrown over the wound and the operator's hands, and the fluorescent screen held over the limb. It was then often possible to seize the bullet and either withdraw it or fix it so that it could be removed with but little further dissection. They had employed antitetanic serum freely with no bad results, and he thought, therefore, that this valuable prophylactic might well be given as a matter of routine. To reserve it for the more severe cases was, he thought, illogical, as it was impossible to determine which cases had been infected with tetanus, and the risk from a small septic wound was not appreciably less than that from severest laceration. As a result of the disaster to the *Amphion* they saw a very curious type of burn from exploding cordite. This was very extensive but extremely superficial, with sharp borders where the clothing protected the part. These healed rapidly and without contracture, the resulting skin resembling an old X ray burn. In conclusion, he would like to mention the excellent results which had followed two operations performed at sea on the hospital ship *China*. One of these was a case of depressed fracture with hemiplegia, which was trephined by Mr. Fedde Fedden; the wound had now healed and the patient completely recovered. Another case was an amputation for an acute emphysematous gangrene of the arm, which had also healed and made an excellent recovery. The success of these two cases was of itself almost sufficient reward for the care and money which had been expended in the equipment of this ship, under the command of Fleet-Surgeon Bolster, R.N.

---

[1] THE LANCET, July 18th, 1914, p 168.

Sir FREDERIC EVE said that among the wounded they encountered degrees of septic infection rarely, if ever, seen in civil life. These were, of course, chiefly after shell and shrapnel wounds. In some instances of persistent suppuration examined bacteriologically cultures had always shown streptococci, and in one case B. pyocyaneus. Gas abscesses, probably from B. aerogenes, also occurred in limbs. Needless to say, frequent irrigation with antiseptics, antiseptic baths, &c., were necessary for septic cases. For baths he used a 1 in 10,000 solution of biniodide of Hg. Owing to fighting taking place largely in trenches wounds of the upper extremities, especially of the hands, were very common. There were also many rifle bullet wounds about the root of the neck and shoulders. In these concussion paralyses of a transient character were observed, from the bullet passing in contact with the cords of the brachial plexus. In one case of rifle bullet wound in this region the missile entered on the left side of the neck, paralysing the left recurrent laryngeal nerve, traversed the neck, and emerged behind the right shoulder, without apparently injuring any other important structure. Concussion paralysis of the central nervous system was of interest because it was not seen in civil practice. He quoted a case in which a shrapnel bullet lodged over the junction of the right laminæ of the twelfth dorsal and first lumbar vertebræ, causing complete paraplegia with the exception of the retention of sensation to light touch over the left lower extremity except the foot. The laminæ were not fractured. Nine weeks after the injury power of voluntary micturition was regained, but there was otherwise very little improvement. Time only would show what amount of repair would take place. The experiences of the South African war showed that, in some of these injuries by concussion alone, there was found after three weeks degeneration of the grey matter of the anterior and posterior cornua, whilst in six weeks to two months the cord was converted into a custard-like mass. A somewhat similar injury to the cortex of the brain appeared to have occurred in a shrapnel bullet wound over the left parieto-occipital region, causing right hemiplegia and hemianopsia. At an operation performed abroad a stellate fracture of the skull was exposed, but no depression or injury to the dura. Rapid improvement took place, but nine weeks after the injury there were still weakness of the right side of the face, right arm and leg, profound loss of sensation on the right side, and right hemianopsia with partial mixed aphasia. Skiagrams of two cases of explosive fracture of the femur were shown. In one, union took place in five weeks with only half an inch shortening. Skiagrams of three cases of fracture from projectiles of the lesser trochanter were shown. In all, the missiles—a piece of shell and rifle bullets respectively—were allowed to remain *in situ* and the wounds healed readily, the foreign bodies causing no inconvenience. In two of the cases there was ultimately only 1¼ inch shortening. All the cases of fracture of the femur were treated with Hodgen's splint. Three cases of suppuration of the knee, elbow, and ankle joints treated by incisions, drainage, and irrigation did well. Having treated seven cases of wound of the chest with involvement of the lung, he had been impressed by the small amount of inconvenience produced by a considerable effusion of blood into the pleura, sometimes associated with pneumothorax. For example, an officer received a rifle-bullet wound of the shoulder, which traversed the upper part of the pleura and injured the lung. Skiagraphy and auscultation showed the existence of pneumothorax with hæmothorax as high as the angle of the scapula. No vesicular breath sounds but only distant bronchial breathing were heard. This patient suffered no inconvenience except some shortness of breath while he was proceeding on foot to the dressing station—a distance of half a mile. There was a fair amount of hæmoptysis on the first day, and slight for the three following days. The speaker had only had one case of tetanus which originated from a very slight and aseptic wound of the leg caused by a small piece of shell which was embedded in the tibia.

SECOND INTERNATIONAL EUGENICS CONGRESS.—It had been decided to hold the Second International Eugenics Congress in New York in September, 1915, but the committee now find it impossible on account of the war to arrange for it to be held at that date. The First International Eugenics Congress was inaugurated under the presidency of Major Leonard Darwin in London from July 24th to 30th, 1912.

ENTERIC FEVER AT ST. BURYAN.—As already recorded in our columns, there has been recently an outbreak of enteric fever at St. Buryan, Cornwall, 50 cases having been notified with six deaths, and there appears to be a considerable amount of dissatisfaction that the epidemic had not been more promptly dealt with at the outset. This opinion was expressed at the last meeting of the Cornwall county council, and the Hon. John Boscawen said he could not suggest a remedy unless it was that whole-time medical officers of health should be appointed for each district. A member proposed as a protest that the salaries of the responsible officials should be reduced by the amount of the county council contributions, and that a recommendation to that effect be sent to the Local Government Board. This was carried with one dissentient.

Reviews and Notices of Books.

A Text-book of Military Hygiene and Sanitation.

By FRANK R. KEEFER, M.D., Lieutenant-Colonel, Medical Corps, United States Army. Illustrated. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 305. Price 6*s.* 6*d.* net.

THIS little book, by the professor of military hygiene in the United States Military Academy at West Point, is evidently intended as an elementary introduction to the study of the subject for the use of combatant officers. The subject is clearly treated in a popular manner. The first four chapters give sound advice on the care of troops, recruits and recruiting, personal hygiene, and physical training. The limits of age for recruits in the United States army are 18 and 35 years; the author, from a physiological standpoint, would make 22 the minimum age. Preventable diseases are next dealt with. Antityphoid inoculation is strongly commended. In both army and navy it is now compulsory for all officers and men under 45 years of age who have not had the disease. A few words are said as to the causation of the various specific fevers, but no directions are given as to preventive measures, and it cannot be said that the pages dealing with this part of the subject are of much value. With regard to cholera, for instance, something might have been said, easily intelligible to a non-medical person, as to commonsense measures of prevention. Heatstroke is mentioned, but hardly anything is said as to its causation or how to prevent it. With regard to wool as a material for clothing, its property of heat conservation "makes it most valuable in cold climates, and even in hot ones it is not altogether undesirable." This is indeed a very mild way of putting it. The section on soldiers' boots (or shoes) is excellent, as is the chapter on water-supply. Various methods of sterilisation are described, and boiling is considered to be "the safest, simplest, and most uniformly available." Stress is also laid on the necessity for careful inspection of the source and surroundings of a water-supply, as being the best guide as to its purity. One or two expressions might be corrected; the term protozoa is not applied to the lowest "class" in the animal kingdom (p. 61); neither is it correct to call anopheles "a variety of mosquito which has rather numerous species" (p. 74). The chapter on the use of alcohol is strongly worded, and yet the question is discussed temperately; the author's general conclusion is that "under normal physical conditions alcohol is never necessary, and is usually undesirable."

Genito-urinary Diseases and Syphilis.

By EDGAR G. BALLINGER, M.D., Adjunct Clinical Professor of Genito-urinary Diseases, Atlanta Medical College, &c., assisted by OMAR F. ELDER, M.D. *The Wassermann Reaction.* By J. EDGAR PAULLIN, M.D. Second edition, with 109 illustrations. London: Butterworth and Co. 1914. Pp. 529. Price 16*s.* net.

MUCH progress has been made in the branch of surgery treated in this volume since the first edition appeared, and care has been taken in this issue to include all of the many advances which have taken place. Thus the modern treatment of gonorrhœa is described, the value of vaccine therapy is discussed, and the phthalein test of the functional activity of the kidneys is given fully and stress is laid on its importance. Sections are also devoted to pyelography, the spirochæta pallida, and to salvarsan and neosalvarsan. A special chapter on the Wassermann test has been contributed by Dr. Paullin, who has succeeded in rendering this important test as simple as its natural complexity allows.

Les Universités Allemandes au XXe Siècle.

Par Dr. RENÉ CRUCHET. Paris: Armand Colin. 1914. Pp. 450. Price 4 francs.

THIS book, which was published before the war began, contains many sidelights of special interest at this time. Dr. Cruchet has made investigations during a period of some 14 years into the 20 universities which Germany possesses at the present day, and has embodied the results of his studies in a very interesting book. He began with Bonn, which he visited for the first time in 1900. At Bonn the medical faculty is of less importance than the faculties of theology, law, and philosophy, but the general impression that the place gave to Dr. Cruchet was military. "If," he says, "pacific ideas are spreading among the younger generation of Germany, they must not be looked for in Bonn, where you can almost smell the powder." He revisited Bonn in 1909 and went over the new hospital under the guidance of Professor Siegert, a celebrated physician and accomplished linguist. Dr. Cruchet describes how the learned professor's conversation drifted from purely medical matters into a discussion of the relations between Germany, France, and England; how he pointed out that Germany's one idea was to be friends with France, that England was the real enemy, and Italy untrustworthy. Dr. Cruchet goes on to say that this conversation is an excellent picture of the actual state of feeling at the universities in general, where ideas of blatant pangermanism (*pangermanisme outrancier*) are daily gaining ground. It appeared to him that the offer of friendship towards France was really only an engine of war directed against England. Although all sections of Germans talk about peace, continues Dr. Cruchet, "when even medical men, on the subject of peace, use such language as I have recorded, one cannot help feeling a little dubious."

We need not follow Dr. Cruchet on his pilgrimage to all the 19 other universities, but his visits to Berlin, Leipzig, Jena, and Strasbourg seem particularly interesting. Berlin as a city did not appeal to him, but he was struck by the great improvements in hospital accommodation which had taken place between 1902 and the present day, and, above all, by the Empress Frederic's Post-Graduate Institute, which was opened in 1906.

At Leipzig he found much to admire in the various clinical buildings of the university, but he notes that the physicians and surgeons have an enormous number of patients to look after. Thus Trendelenburg had 400 beds and Curschmann no less than 700. Dr. Cruchet relates a story to the effect that Curschmann one day implied to a colleague, who was professor at a small university, that he had plenty of time to go round his wards in the morning, whereupon the colleague said: "I suppose you go round your wards in a motor-car."

Jena, a university founded in 1557, reached a high level of fame during the reign of the Grand Duke Charles Augustus of Saxe-Weimar (1775–1830), when among its professors were Schiller, Hegel, and Hufeland, the physician. New university buildings were opened in 1909. Jena is unique among universities in that it is intimately connected with, and partially subsidised by, a celebrated scientific and eminently successful commercial firm—namely, the great house of Zeiss. Dr. Cruchet gives a long and most interesting account of the founding of this firm, of its relations with the university, and of the work, both scientific and social, carried on thereby.

Strasbourg naturally filled Dr. Cruchet with very mixed emotions. His trained intellect cannot refrain from admiration of the magnificent buildings of the new German university commenced in 1872, and the newest portion of which, the children's clinic, was opened in 1910. There are four faculties besides medicine, but by far the most important buildings are devoted to medicine and its accessories. The university possesses its own heating, lighting, and power plant, a bakery, a butchery, a laundry, and machine sewing shops—in one word, the note of the university is "thorough."

Dr. Cruchet discusses the German opinion that Germany is the greatest country in the world, and that France is a decadent nation. He tells us that when he and some other French medical men visited the university and the hospital buildings in 1912, the director who showed them round casually remarked as they passed through the bakery, "We can bake enough for six army corps here." Thus, says Dr. Cruchet, even the hospitals, places of peace *par excellence*, are all organised so as to serve when the day comes as bases of supply and revictualling. The final chapter of the book is devoted to a comparison between the decentralised scheme of German university education and the centralised scheme in France, and Dr. Cruchet finds that the German is by far the better.

The whole book is one deserving careful study; it is written by a trained observer, and it is scrupulously fair. Germany is a great country. All her methods do not commend themselves to us, but her foresightedness is worthy of imitation, and the right attitude of other countries towards her may be summed up in the words of the elderly lady of Early Victorian days, who at a prayer meeting of intimate friends observed, "My dears, if we were all as painstaking, as patient, and as quick to seize an opportunity as is the Devil we should all be the better."

The Mental Deficiency and Lunacy (Scotland) Act, 1913 (3 and 4 Geo. V. Cap. 28).

With Introduction, Notes, and Appendices by J. EDWARD GRAHAM, K.C. Edinburgh and Glasgow: Willian Hodge and Co. 1914. Pp. 303. Price 12*s.* 6*d.* net.

FOR Scotland a Mental Deficiency Act was required and was passed, as was done in the case of England, in order to give effect to recommendations made by the Royal Commission appointed in 1904, but in the case of Scotland opportunity was taken to make various amendments in the existing lunacy laws. Hence the title of the Act, Part IV. of which applies to the latter branch of its subject matter. Differences of administrative machinery and in the laws in force regarding lunacy in England and Scotland explain the necessity for separate Acts in the two countries dealing with a subject the importance of which is equally realised in both, similar principles being observed in each statute. The "General Board of Commissioners in Lunacy for Scotland," now known as the General Board of Control, is strengthened by the addition of a medical member, and not more than four medical deputy commissioners, one at least of these being a woman, take the place of the two deputy commissioners provided by the existing Scottish Lunacy Acts.

In Scotland, as in England, a large number of officials and public bodies will have to familiarise themselves with a new machinery, with financial questions, and with duties defined by law, before any general improvement of the condition of the mentally defective can be achieved, and Mr. Graham's book is a carefully and very conveniently arranged text-book which should be found useful by all, including medical practitioners, likely to require its guidance. The latter will find, for example, some useful observations upon the different forms of certificate applicable to lunacy and mental deficiency at the end of the author's clear and instructive introduction, supplemented by notes which are of a critical as well as explanatory character, where certificates are dealt with in the sections of the new statute. The author, it may be mentioned, does not conceal his opinion that a certain amount of haste in getting the measure through Parliament has left traces upon its drafting in places, to some of which he calls attention, and he justifies his observations by the instances cited. He has compiled what should be a helpful work of reference in connexion with its subject fully supplied with appendices, to which no doubt addition will have to be made in future editions, as fresh regulations are added to those already issued.

MISCELLANEOUS VOLUMES.

Dr. Finny's First Aid (London: Thomas Murby and Co. 1914. Pp. 33. Price 6*d*. net) is a useful note-book for ambulance students. It contains the principal facts of anatomy and physiology, various kinds of injuries, and their first-aid treatment, arranged by a lecturer on first aid at Kingston-on-Thames Technical Schools, and interleaved for notes.——Another useful little book on the same subject is *Why and Wherefore in First Aid*, by Dr. N. CORBET FLETCHER (London: John Bale, Sons, and Danielsson, Limited. 1914. Pp. 84. Price 6*d*. net). The question-and-answer method as applied in this little book serves a double purpose. For instance: "In stomach bleeding, why is blood dark and like coffee-grounds?" Answer: "The stomach juices act on and alter the hæmoglobin of the blood." In this case the question directed towards the explanation of a fact would tend with many persons to impress the fact itself on the mind more effectually than would such a question as "What is the character of the blood in stomach bleeding?" But really this is a matter of personal idiosyncrasy in the reader.——A practical little addendum to the first-aid library is Miss THEKLA BOWSER'S *The Whole Art of Bandaging* (London: John Bale, Sons, and Danielsson. 1914. Pp. 108. Price 1*s*. net), which shows throughout the results of her personal experience as a nursing sister of the St. John Ambulance Brigade. It contains many excellent and accurate illustrations.

Mother-craft for Schoolgirls, by FLORENCE HORSPOOL (London: Macmillan and Co., Limited. 1914. Pp. 57. Price 1*s*. net), is the result of the author's own experience as infant visitor to the Swansea corporation, and subsequently of three years' conduct of a "babies' welcome" at which young girls about to leave the elementary schools were trained in the craft of rearing the baby. It gives a description of the methods used in the classes there. The subjects dealt with are washing, weighing, dressing, and feeding the baby, the feeding of the nursing mother, sleep and fresh air, flies, food, baby's ailments, and so forth. Lady Mond contributes a preface. The book is written in simple language in graphic conversational form and is well illustrated. It can be commended.

The perennial *Chavasse's Advice to a Wife* (London: J. and A. Churchill. 1914. Pp. 348. Price 1*s*. 6*d*. net) now appears in its sixteenth edition and 420th thousand, revised by Dr. STANLEY DODD, assistant obstetric physician to Westminster Hospital. This venerable book, which has dissipated the fear of the unknown in maternity and given confidence to many generations of young wives, has been carefully brought into line with modern knowledge, and considerably pruned of its redundancies, without, however, any ruthless sacrifice of its quaint originality. A useful section on sexual hygiene has been added.

The only material other than official information contained in the *Hunterian Society Transactions, Sessions 1910–11, 1911–12, 1912–13, and 1913–14* (London: Headley Brothers. 1914. Pp. 76), edited by Dr. J. TYLOR FOX, consists of an account of the discussion on the uses of tuberculin that took place on March 27th and April 9th, 1913.

JOURNALS AND MAGAZINES.

Brain: A Journal of Neurology. Edited by HENRY HEAD. Vol. XXXVI. Parts 3 and 4. 1914. London: Macmillan and Co., Limited. Price 4*s*. net, or 10*s*. 6*d*. per annum.—This double number of *Brain* contains matter of great interest and importance which appeals both to neurologists and alienists. Dr. David Orr and Dr. R. G. Rows contribute a paper on Lymphogenous Infection of the Central Nervous System, which includes clinical and experimental proof of the importance of the lymphatic system as a vehicle of infective material. It also shows the histological changes which take place as a result of such infection and the manner in which vascular lesions may secondarily arise. Incidentally, therefore, the experiments make clear the mechanism of the production of spinal cord lesions in diseases such as tetanus and rabies.—Dr. Musken's article on a Study of the Posterior Longitudinal Bundle in Relation to Forced Movements is too technical to lend itself to detailed criticism. It seeks to show by experimental and histological examination the intimate connexion of the various structures concerned in equilibration with the posterior longitudinal bundle.—Dr. S. A. K. Wilson's extremely interesting and complete article on the Anatomy and Physiology of the Corpus Striatum, a record of experiments on the monkey, is a very important contribution, and is in many ways supplementary to the same author's monograph on Progressive Lenticular Degeneration.[1]—Professor Mingazzini's article on Aphasia Due to Atrophy of Cerebral Convolutions, without any focal lesions, directs attention to a class of cases of much importance both medically and legally.—Dr. F. E. Batten and Dr. Douglas Wilkinson describe an unusual type of hereditary disease characterised by mental as well as physical symptoms, and Dr. Orton, from the laboratory of the Worcester State Hospital, Massachusetts, contributes a Study of the Satellite Cells in 50 cases of mental disease.—The editor is to be congratulated on an exceptionally interesting issue.

The Burlington Magazine.—The November number of this excellent periodical contains an instructive article by Mr. Arthur Gardner on the sculptures of Rheims Cathedral, the primatial church of France, of which he writes that it "had very good claims to be considered the finest of all French cathedrals, and as such perhaps the supreme artistic creation of the human race." The article is accompanied by some excellent reproductions of photographs of the numerous splendid sculptural groups which adorned the cathedral and especially the magnificent porches, and makes sad reading, as it is impossible not to recognise that hopeless damage must have been done to the building, even though much, or indeed all, of the main fabric may be standing and stable. And the latter supposition is optimistic. An illustrated record of various famous works of art in Belgium is contained in the same number. The loss of life in war, and the unspeakable misery and heavy mortality that follow on its devastating operations are things which must come first in the medical mind, as, we believe, they also come first in the mind of the most enthusiastic connoisseur. But Belgium contains the epitomised lives of artists who have earned immortality, and the destruction of this work is in a sense recent murder. Milton said, "As good almost kill a Man as kill a good Book," thereby recognising the crime of intellectual assassination.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 21, 1914.

Our Belgian Colleagues.

THE utter ruin which has fallen upon so much of gallant Belgium has destroyed the whole machinery of the medical profession and its adjuncts in that country. There exists no longer in Belgium a medical profession which can either cope with the misery and sickness of the inhabitants who remain, or make any attempt towards the protection of those who may return. We publish in another column an appeal from Professor JACOBS of Brussels, who points out in clear and moving terms the terrible position in which his colleagues and also the pharmacists of the country are involved. The majority of those living in the towns and villages that have been pillaged and burnt are utterly ruined. They can do nothing without help either to assist the population in its present plight or to ward off the effects of epidemic disease. No one can read the appeal without seeing how pressing is the need for immediate aid, and we trust that the Belgian profession will not turn in vain to their British brethren.

A committee has been formed, as has been announced, whose object is to give immediate succour to Belgian medical men and Belgian pharmacists to such degree as the circumstances of war permit. A letter this week from representative members of that committee announces the beginning of the work and appeals for subscriptions. For the moment the giving of assistance at once to the members of the medical and pharmaceutical professions in their daily work is being considered. That much more than this will have to be done, when the time arrives for the complete rehabilitation of this utterly brave and utterly miserable people, is clear. In the great settling up international arrangements will see that the Belgian medical profession is restored completely to its former distinguished place. And before that day arrives it may be feasible to organise a world-wide scheme to better the medical position in Belgium. But at the present moment money is wanted to maintain alive the sick and those who alone can aid them. The inhabitants of the greater proportion of Belgium—those, that is, who remain—are destitute, while the homes of many of them have been burnt or so wrecked and pillaged that the remnants are uninhabitable. The people are enfeebled by misery, shock, and ill-treatment, and as winter approaches many of them will assuredly fall a prey to the first contagious disease that attacks them, while the environment in which they live is congenial to the breeding of any infection. Prompt medical treatment is necessary to succour them, and the strictest care will have to be exercised to protect them from the onslaughts of epidemic disease. And the doctors and pharmacists on whom the task devolves are themselves as ruined as their ruined patients. They are quite helpless to discharge their duties unless material aid is promptly found for them, and the majority of them who remain in the country are unable to maintain an existence there. Their source of income is gone, their surgeries and offices have been destroyed, while the laboratories and business premises of the pharmacists have also perished on all sides.

The situation is so appalling that any attempt to describe it appears to belittle it, while the plight of the Belgian doctors and pharmacists who are here among us as refugees is also truly deplorable. We sincerely trust that our readers will do their best, sorely tried as many of them are by the events of the war, to respond to the plea of their Belgian colleagues. We cannot at once rehouse the Belgian doctors or place the Belgian pharmacists in the position that they enjoyed formerly, as the result of any appeal for money. We know that, though we all believe that these things will follow in due course. The immediate necessity is to help the Belgian doctors and pharmacists as far as the conditions of war permit, so that they in their turn may help their stricken compatriots. Let us all give what we can, for it is our bounden duty so to do.

◆

Soldiers, Soldiers' Wives, and the Liquor Traffic.

IT appears to be beyond question that a substantial and regrettable amount of intoxication is to be observed at the present time among the wives and dependents of soldiers serving with the colours and also among soldiers now undergoing training in the various centres throughout the country. As a remedy the principal suggestion seems to be that public-houses, either everywhere or in particular districts, should be compelled by law to open later and close earlier. To open them at midday and to close them at 8 or 9 P.M. would be to follow some, at least, of the plans proposed. This method of dealing with the question is, however, liable to sound if obvious criticism. Although to curtail the hours of opening does clearly lessen the period during which persons inclined to drink in public-houses are able to do so, and to that extent saves them from temptation, at the same time, the temptation will still be there when the prescribed hour strikes, and anyone who desires to drink to excess will still find ample time to do so unless his or her occupations prevent it. Soldiers, it may be remarked, do not get much opportunity to drink before midday, and soldiers' wives in most instances will not be prevented by business from becoming intoxicated at some time before 9 P.M. Nor will the latter class as a rule be saved from the opportunity and temptation to drink in their own homes by shorter hours of opening for licensed houses. Such a step would, in short, be nothing more than a palliative of a partial character for an evil which, where it exists, is no doubt of serious consequence to the individuals immediately affected as well as to the community.

The evil has different causes in different classes, and it is quite possible that the degree of its prevalence is liable to be exaggerated. Among women, wives of men serving, who receive a separation allowance, there are two contrasting conditions observable, which may be summarised by saying that some are pecuniarily worse off owing to their husbands' absence, while others are better off than when the wage-earner was with them. These last are the wives of men who when at home, either from selfishness or poverty, or perhaps prudently, keep them short of money, and it is probable that the women who are stated to have "taken to drink" belong largely to this class. Many women, too, no doubt, are feeling lonely and depressed without their husbands, while at the same time they have less work in their homes to occupy them; or perhaps if they have been earning money for themselves have been deprived of their usual occupations through the war. The problem of assisting women in such circumstances without depriving them of their justly due pecuniary allowances is not an easy one to solve, but it is to be hoped that influences may be brought to bear in their behalf which will stem the evil more effectively than the closing of public-houses for a few hours can ever do. It is also to be hoped that the weakness of a comparatively few who attract attention by public misconduct will not be mistaken for a vice affecting a large class which deserves our warmest sympathy. Thousands of soldiers' wives are now living their lives in circumstances of penury, deprived of husbands whose wages before the war were maintaining them in comfort. Thousands also are being made widows, and there is a field for benevolent enterprise among the "deserving" and "undeserving" alike (if such rough classification is permissible) which will long give scope for the energies of more kind-hearted persons than are likely to be found to occupy it. With regard to soldiers, and particularly those newly recruited and undergoing training, there is also the likelihood that the weakness of the few will be assigned as a characteristic to the general body. Here again there is a very immediate need for the assistance of the benevolent, given either in a pecuniary form or in that of personal work. The Young Men's Christian Association and other agencies are doing their best with this object in circumstances of exceptional and peculiar difficulty. Recruits are being trained in large masses, in localities where the opportunities for healthy recreation after violent and sustained exertion are few, and under conditions which are in many instances those of great discomfort if not of actual hardship. It may be highly desirable to forbid them to frequent public-houses after certain hours, or to close those houses earlier than is now done, but it is far better to benefit all alike by providing counter attractions, and opportunities for obtaining wholesome and attractive food and drink wherewith to supplement the meals furnished by the authorities. Moreover, it is to be hoped that as the season progresses the hurriedly improvised accommodation and commissariat of our training camps will be improved and reorganised so as to diminish still further the temptation to have recourse to the wet canteen or the public house.

The conference which took place last week at Caxton Hall, Westminster, under the chairmanship of the Archbishop of CANTERBURY, to consider the problem of alcohol and its relation to the war, was in many ways unprecedented. Discussions of temperance questions have often been a cause of acrimonious controversy among people who admittedly desire the national well-being, but who do not agree as to procedure. Few things are more significant than the way in which men and women of all classes and shades of opinion have been aroused to see the grave peril which faces a nation, which is in the throes of war, in connexion with the abuse of alcohol. One of the last, if not the last, appeal made by Lord ROBERTS was with reference to the subject of treating soldiers, and that he had intended to be present at the conference shows his remarkable prescience in all things that pertain to the welfare of the soldier. The conference was convened by the Bishop of CROYDON, and included among the speakers a number of well-known members of the medical profession, other selected speakers being representative of various interests in religious, political, and social life. It was decided, we believe, by those who planned the conference that questions of legislation should not be dealt with in the resolutions which were to be considered, important though this side of the question undoubtedly is. Many of the speakers referred to it, but attention was confined to what may be called the social aspects of the problem, which in a democratic country are of the greatest importance. Emphasis was therefore laid upon two lines of reform which are the counterpart of one another—viz., a pledge of total abstinence for the duration of the war, and a determined effort to supply the wants of soldiers, sailors, and civilians for suitable recreation and refreshment, apart from temptations to drink.

Annotations.

"Ne quid nimis."

LORD ROBERTS.

Lord Roberts has died, as he doubtless would have wished to die, in harness. What more glorious end could he have had to a long, honourable, successful, and unstained career than to pass peacefully away in performing the great service of heartening his beloved troops in their terrific struggle? This "heartening" faculty of his was conspicuous throughout his career. He applied to all the affairs of men with which he was called on to deal the great principle that is the keynote of modern medicine: "Support the strength and aid Nature to do her beneficent work." Among other visits paid by him in France he inspected an Indian hospital ship in port, and there, as among his Indian troops, the worship and affection with which he was regarded was evidenced in a striking degree. The explanation of this whole-souled devotion to his person that always enveloped him is perhaps to be surmised from the graciousness of his commendation of the hospital ship to its commanding officer: "Your hospital is as near perfection as any I have seen; I congratulate you, sir." Few people, we believe, are aware of the intimate tie that linked him with our profession in that on Jan. 10th, 1901, he was admitted an honorary Fellow of the Royal College of Surgeons of England. And, indeed, as a soldier Lord Roberts excelled in just those qualities that should characterise the ideal medical man—patient and enduring under trial, alert and prescient against unexpected sources of danger, a past-master of his craft, keeping himself ever abreast of its development under rapidly changing conditions, courageous, confident, and resolute in carrying out his carefully thought-out plans, resourceful in emergency, above all petty feeling, humane and love-inspiring in his dealings with all, and relying both for guidance and for justification on the spiritual and moral force that informs the universe. He was truly a great soldier, a great man, a great example; that he should be buried beneath the dome of the metropolitan cathedral of St. Paul, in proximity to Nelson, is a fitting close to his priceless life-work.

THE END OF THE POLYCLINIC.

MANY London practitioners have lately learnt with regret that the Medical Graduates' College and Polyclinic, with which Sir Jonathan Hutchinson's name will always be associated, has ceased to exist. A general meeting of members and subscribers was held at the College, 22, Chenies-street, W.C., on Oct. 28th, when Dr. C. O. Hawthorne, chairman of council and editor of the *Polyclinic*, presided. Dr. Hawthorne explained that the meeting had been called to consider the situation of the College in so far as this was affected by the war. In view of the existing financial position the council were of opinion that the College could not be continued. In its early days the Polyclinic acquired a burden of debt from which it had suffered throughout its career. A scheme for putting it upon a secure basis had been in contemplation, and had times continued normal the council felt confident of carrying this through with a fair prospect of success; but all these plans had been brought to nothing by the unusual circumstances produced by the war, and there was now no option but to close the College. Mr. Lockhart Mummery, the honorary treasurer, then presented a financial statement and expressed the hope that there would be just sufficient funds to meet all liabilities. Dr. Dundas Grant thereupon moved a resolution, which was carried unanimously, approving the council's action in deciding to close the College and authorising the assignment of the lease of the premises to Sir Jonathan Hutchinson's trustees in satisfaction of their claim against the Polyclinic. We feel that the decision of the council, endorsed by the meeting, is the only business-like course to take in view of the financial position of the College. In happier circumstances the Polyclinic might have continued its useful activities on behalf of post-graduate medical education; but it was encumbered with a heavy debt from the beginning, and the complication of the war made its end inevitable.

MEDICAL CHARACTERS IN CHINESE WRITING.

CHINESE writing is a sealed book to by far the majority of the inhabitants of these islands, whose sole acquaintance with even the appearance of the "lettering" (if we may call it so) is confined to marks on pottery, jars of ginger, or chests of tea. Dr. Lucien-Graux, director of the *Gazette Médicale de Paris*, has just issued a most interesting book dealing primarily with Chinese medical characters, but prefaced by a general description of the innate quality (*génie*) of Chinese writing.[1] Chinese characters are not letters but a kind of picture, and in addition to each picture there is a "key picture" which is invariable for all words of the same class. Thus, to give Dr. Lucien-Graux's example, the words calf, ox, cow, bull, heifer, all belong to the same kind of animal, but there is nothing in the letters or syllables which make up the different words to show this. In Chinese, however, all these animals are expressed by different characters, but all these characters have as a portion of their composition a character signifying "bovine race." To make the matter more clear we may refer to one of the few instances of picture writing in English. Most travellers by train will have noticed here and there along the side of the line a large white painted board bearing on it in black a design like this 〰〰〰〰〰〰; when the engine driver sees this he knows that he is approaching a water trough, from which he may take up water during the run. Now if English were written on the Chinese system all such words as ice, snow, rain, mist, pond, fountain, dew, and so on, would be prefaced by 〰〰, the water sign, and any foreigner who knew the key word would at once know that any one of the words mentioned above would have to do with water. There are in use in Chinese writing 214 of these key characters. The medical one is No. 104, and it is made up of two symbols, the one meaning "man," the other, "board" or "plank." These combined mean a man in bed, otherwise ill. To this key character others are added descriptive of various diseases or diseased conditions, but it is difficult to describe them in words without reproducing the characters, however we may attempt one or two. Baldness, for instance, is signified by the "ill" key character in Chinese, Ni;

---

[1] Les Caractères Médicaux dans l'Écriture Chinoise. Par Dr. Lucien-Graux. Paris: A. Maloine. 1914. Pp. 276. Price 4 francs.

and a symbol representing a reaped field; jaundice is represented by the "Ni" combined with a symbol representing a ploughed field—i.e., the colour of bare earth. All symbols are not as clear as these two, however, for, to take one at random, dysuria is expressed by Ni and another symbol representing two trees with their branches joined. Why this symbol should have been chosen is, says Dr. Lucien-Graux, a mystery. There are two addenda to the main portion of the work, the one a list of Chinese drugs and materia medica which is mediæval, and the other a translation of a very ancient Chinese document by an unknown writer giving a somewhat pessimistic, but at the same time noble, view of medicine. The writer begins by saying that medicine can only work in accordance with the inscrutable laws of Heaven; for man the mysteries of birth and death are unsolved, and medicine cannot save from death, a truism which was expressed in mediæval times by the line, "Contra vim mortis non est medicamen in hortis." "But," continues the Chinese writer, "the rôle of medicine is all the same an admirable one. She can prolong life, she can heal the multitude of evils which afflict poor humanity, she can fortify morality by preaching virtue and proscribing vice (that mortal enemy to health), and finally she can consolidate nations and peoples by hygienic counsels and recommendations." These are noble words, and with them we take leave of a remarkable work.

A STATE-AIDED INDUSTRY.

THE chemistry of coal-tar colours is so closely allied to that of synthetic drugs and fine chemicals used in medicine that the Board of Trade scheme for encouraging the permanent manufacture of dye-stuffs in the United Kingdom must inevitably promote the synthetic drug industry which until quite recently was wholly neglected in this country. The German firm which introduced diethyl-barbituric acid (veronal) and acetylsalicylic acid (aspirin) into medicine is as well known for its aniline dyes as it is for its synthetic drugs, and it would be difficult to say whether another famous firm is best known because it makes artificial indigo or because it produces salvarsan. If in Germany the manufacture of synthetic drugs has kept pace with the production of dye-stuffs, there is good reason to expect that the establishment on a proper scientific basis of the colour industry in Great Britain will mark the beginning of a new era for the British drug industry. Briefly, the proposal of the Board of Trade is that a limited company should be formed with a large capital of which the bulk would be subscribed by the consumers of dye-stuffs and others interested; the Government would subscribe a certain portion of the share capital and guarantee the interest on a large debenture issue for a term of years. This proposal is made after consultation with the committee on chemical manufactures appointed shortly after the outbreak of war to consider what steps it was advisable to take to promote the coal-tar colour and fine chemical industry. Seeing that manufacturers of medicinal chemicals were well represented on this committee, it would not be surprising to find when the full scheme is unfolded that provision has been made for the development of the drug section of the industry. No doubt theoretical objections to the State interference in industrial enterprise could be raised, but in the case of the industry in question these must be brushed aside for the substantial reason that without State aid the trade could not be developed. Without State encouragement the German chemical industry would never have reached its present vast dimensions, and it is obvious that our manufacturers could not successfully compete with an organisation which has taken Germany more than 40 years to bring to a state of perfection if the Government were to remain indifferent. The overhauling of our methods of chemical education, the removal of obstacles to the use of cheap denatured alcohol, and some modification of our patent law are among the reforms which must inevitably accompany the successful development of this industry, and since a Government department has undertaken to encourage this development these reforms will no doubt be hastened.

TREATMENT OF SNAKE-BITE.

IN the *Indian Journal of Medical Research* (1914, vol. ii., pp. 46–148) Captain H. W. Acton and Captain R. Knowles publish some important investigations into the nature and suitable treatment of snake-bite. In different varieties of snakes the toxicity of the venom varies. The common cobra, *Naia tripudians*, is *the* poisonous snake of India, and this because of its wide distribution and the volume of venom it gives with its bite. The hamadryad, or king cobra, a rarer snake, is also highly lethal. The bite of many of the vipers is fatal, but often after a longer lapse of time. The cause of death after viperine bites may be through local thrombosis, which may lead to pulmonary embolism; more usually it is due to multiple capillary hæmorrhages from the mucous membranes and internal organs. Sometimes death follows from secondary causes such as gangrene. The cobra venom acts differently. It contains two elements, a hæmolysin and a neurotoxin. The latter is the fatal factor. It causes paralysis of the respiratory centre in the medulla, paralysis of the nerve-endings in the diaphragm and respiratory muscles, and death from asphyxia. The shortest period within which death can occur after a cobra bite is about 30 minutes; the longest recorded was 30 hours. As to treatment, the usual remedies have been investigated experimentally in turn and the findings have much practical significance. 1. Ligature: In cobra poisoning the effect is merely to delay the onset of death by preventing the venom from at once getting into the circulation; it is wholly insufficient to save the life of the patient. In viperine bites, however, it will in some instances save life, even though no other measure be used; in others it will greatly prolong life. The local thrombosis induced tends to localise the venom and affords assistance to the application of local remedies. 2. Amputation: Value in cobra bites strictly limited. It must be performed within a few minutes or it is ineffective. In the case of such a bite, however, immediate ligature and amputation is the best line of treatment. 3. Limb compression fails to yield better results than simple ligature. 4. Incision into the bitten site appears to be of not much value, the difficulty being, apparently, that the venom is colloidal in character and being viscid is extremely difficult to express. 5. Much interest attaches to the observations made upon the supposed value of certain drugs, especially potassium permanganate. This drug in the form of crystals is widely used abroad, and is held in a small case, also enclosing a lance. On being bitten it is advised at once to enlarge the wound with the lance and then rub in some of the crystals. This method of treatment is here practically condemned. It is held that supposed "cures" by such means fall into the category of non-lethal cases. It is better to inject subcutaneously 10 c.c. of a 5 per cent. solution of this salt; or, better still, 10 to 20 c.c. of a 1 to 5 per cent. solution of gold chloride. The advantage of the subcutaneous method is that it allows the drug to maintain longer contact with the venom than if the wound is enlarged. There is, however, difficulty in injecting much fluid into a part such as the finger or toe. The zinc salt of permanganate is probably preferable to that of potassium.

BROOKSIDE PARKS AS RURAL AIR-SHAFTS FOR TOWNS.

THE supply of adequate open spaces for towns is a matter which is increasingly attracting attention. Of course, in towns and cities already established the question of expense greatly limits the possibilities. In a paper on Open Spaces and Running Waters, read before the Imperial Health Conference last May, which was attended by delegates from Australia, Canada, South Africa, New Zealand, and many of the Crown colonies, Lieutenant-Colonel G. T. Plunkett, C.B., R.E.,[1] introduced some very practical considerations for our future guidance by calling attention to lost opportunities in London. He first recalled the fact that the Fleet River, which at one time was so broad and deep that ships laden with merchandise used to navigate up it from the Thames at Blackfriars as far as what is now Holborn Viaduct, and which was navigable for barges so late as 1652, was covered up and built over by 1766. Had the future growth of the city then been realised it would have been easy and comparatively inexpensive to preserve a stretch of land from one to two or three hundred yards or more wide, from the Thames upwards along the course of each of those streams which fall into it, widening out as they approach the hills to take in the slopes with their woods and ponds. By preserving all these streams and laying out a strip along each bank adequate open spaces would have been afforded, easily accessible to parts of London now practically deprived of park accommodation. Colonel Plunkett rightly points out that a park completely surrounded by houses can never be quite the same as one that communicates with the open country, which would preserve for the inhabitants the sights and sounds of the country as nature made it, leaving the appearance of the land as nearly as possible as it was while yet untouched by man, with its native trees, plants, wildflowers, and insect and bird life. For such air-shafts as are here contemplated would afford sanctuary for many kinds of birds that will not penetrate into the enclosed spaces which constitute our present parks and squares. It would therefore be better, he contends, instead of trying to form a ring of open spaces, necessarily more or less irregular, round a large city, to arrange that these spaces, wherever possible, should radiate from the central and more thickly populated districts and stretch outwards into the country like the spokes of a wheel. A strip of park, with an average width of perhaps only two to four hundred yards, but two or three miles or more in length, extending to the open country, would be far more valuable than an equal area in an enclosed square or circular plot. Even in London the most suitable ground to take up for parks, he considered, would be that along the course of our rivers and brooks; and still more important is it that in newer cities parks should be thus laid out along the banks of rivers and streams. It is gratifying to learn that this principle is being acted on by the Wimbledon authorities in regard to the Beverley Brook.

1000 CASES OF CANCER OF THE STOMACH.

Dr. Julius Friedenwald presents an extremely careful clinical study of gastric carcinoma in the *American Journal of the Medical Sciences* for November, and as it is based on an analysis of 1000 cases it is worthy of serious attention. About 60 per cent. of his patients were males, and a similar percentage occurred in the fifth and sixth decades. Ulcer of the stomach, on the other hand, falls principally on the third and fourth decades. Heredity did not appear to play any part in over 90 per cent. Dr. Friedenwald thinks that his analysis makes for depreciation of the belief that peptic ulceration is an important precursor of gastric cancer, since even the most liberal interpretation failed to discover symptoms of ulcer in more than three-quarters of his cases. The gastric contents were analysed in 733 cases, and in nearly nine-tenths of these no free hydrochloric acid was found. In a majority of such lactic acid was present, also Oppler-Boas bacilli. Sarcinæ were noted in one-third only and "coffee-grounds" in about two-thirds. Occult blood was found in the stools in 92 per cent., and especially in early cases, though obvious melæna occurred in 21 per cent., and hæmatemesis in 25 per cent. only. Pain and loss of weight were the most constant of symptoms, and anæmia was noted in a large majority. Vomiting occurred in nine-tenths of Dr. Friedenwald's cases; in contrast to the clinical picture of gastric ulcer, both pain and vomiting were notably associated with absence of free hydrochloric acid in the stomach contents. In only one-third was the tumour palpable within six months of the onset. In more than half the cases the growth was pyloric. It is surprising to find that fever was noted in nearly half; it is more often a late than an early symptom. In a majority the duration of life from the onset of symptoms was less than 12 months. Of 128 patients submitted to operations other than exploratory (gastro-enterostomy, gastrostomy, gastrectomy), not one was living at the time of the analysis. Dr. Friedenwald therefore urges earlier exploration, recognising the desperate nature of the malady and the hopelessness of the prospect in cases where the diagnosis has become apparent from clinical symptoms alone.

THE discussion on Surgical Experiences of the Present War, which was opened on Monday last at the Medical Society of London, and of which a full report appears in our columns this week, will be continued on Monday, Nov. 23rd, at 8.30 P.M., by Mr. D'Arcy Power, Mr. Charters Symonds, Mr. R. P. Rowlands, Dr. D. Embleton, and Dr. Ironside Bruce.

AT a meeting of the members of the Lister Institute held on Wednesday last the proposal of the Governing Body to amalgamate with the Medical Research Committee, appointed under the National Insurance Act, was rejected.

---

[1] Report of the proceedings of the Imperial Health Conference held at the Imperial Institute, London, May 18th to 21st, 1914. London: The Victoria League, 2, Milbank House.

NOTE ON THE WOUNDS OBSERVED DURING THREE WEEKS' FIGHTING IN FLANDERS.[1]

BY G. H. MAKINS, C.B., F.R.C.S. ENG.,
COLONEL, ARMY MEDICAL SERVICE; CONSULTING SURGEON TO THE FORCES OVERSEAS.

Nov. 12th, 1914.

THE very large number of casualties during the fighting of the last three weeks has thrown immense pressure on the field ambulances and clearing hospitals at the front and also on the base hospitals at Boulogne. The transport of the patients during this period has been much accelerated on the one hand by the fleets of motor ambulances plying between the field ambulances and the clearing hospitals, and on the other by the very much shortened line of communication by rail to the medical base.

Transport Arrangements.

The motor ambulance has fully justified itself in the matter of rapidity and convenience, and although it is not likely entirely to take the place of the horse ambulance, since the latter can be used where the employment of motor vehicles is impossible, yet in the future the number of horse ambulances will no doubt be decreased. The serious disadvantage of motor transport lies in the amount of suffering experienced by the severely wounded; the jolts which on a motor tour only provoke a smile or a growl according to the frame of mind of the tourist as he traverses a stretch of bad surface, prove a terrible experience to the severely wounded man, especially if a fracture is existent. In this particular it is clear that the motor ambulance can never prove a substitute for the more smoothly running ambulance train, and that except in the case of the lightly wounded the portion of the journey performed in the motor ambulance should be kept as limited as possible. For the removal of patients from train to hospital and hospital to ship the motor ambulance has proved invaluable.

The clearing hospital as a unit is working well and has greatly lightened the work which in former campaigns has fallen upon the field hospital. At the same time the duties devolving on the medical officers have been extremely heavy, since at this stage not only have all the wounds been dressed, but many operations have been performed, a certain number of cases have had to be retained and cared for as of too serious a nature to warrant removal to the base, and every patient has received an injection of antitetanic serum, if this has not been already given at the field ambulance.

The ambulance trains are now equal to the necessities of the position, all furnish the primary requirement of intercommunication between the separate wagons, they are well equipped with medical and surgical stores and food, they are capable of being heated, and carry the staff of medical officers, nurses, and orderlies necessary for the care of the men and the dressing of their wounds. Many of the wounded have been arriving at the base well within 24 hours from the moment of reception of their injury. This cannot always be the case, since congestion of the railway may check the progress of the trains, and occasionally difficulty in collection of the wounded men or a temporary stay in the hands of the enemy may involve the loss even of days.

The sudden complete diversion of the line of communication to the new medical base and the consequent need of the establishment of a new series of hospitals has necessitated very strenuous endeavours to meet the wants of the situation, and had it not been possible to transport at once a large number of patients across the Channel, it is difficult to see how the patients could ever have been distributed to the hospitals situated in other parts of France. Happily, in the absence of suitable public buildings of any other nature, the use of the hotels and casinos of the town and its immediate neighbourhood has enabled the stress of work to be dealt with, and ten efficient hospitals are now established.

The Nature of the Wounds.

With the change in the military situation and the character of the fighting, the nature of the wounds to be dealt with has also undergone considerable alteration, the preponderance in the number of shell wounds has greatly decreased, and those inflicted by rifle bullets has risen to probably more than 50 per cent. The wounds are in the main of very severe type; this appears to be dependent on the fact that they have nearly all been received at the short distance of about the 200 yards which separates the opposing trenches, and that many bullets ricochet and acquire irregularity of flight by striking the margin of the trenches. The type of entry and exit wounds is somewhat varied from those produced by the older Mauser and Lee-Metford bullets; there is certainly more irregularity in form and size. One especially striking form is that in which the central round wound has a slit passing from opposite sides, suggesting that the original opening has been enlarged with a knife for purposes of exploration; such wounds are seen mainly on prominent points of the body, such as the margin of the patella or over an outstanding tendon. The number of large stellate exit wounds is also great, the most typical of all being those on the dorsum of the hand. The difficulty of being convinced as to the production of large explosive wounds by rifle bullet, shrapnel bullet, or fragment of shell respectively is very great. The patients positively state many wounds to have been produced by rifle bullets, which offer no resemblance to any type wound. Thus in one instance the whole length of the soft parts of the flexor aspect of the forearm was lacerated and laid bare beneath a persisting bridge of skin formed by two triangles of which the truncated apices were continuous in the centre, while the bases corresponded with the width of the limb at the bend of the elbow and the junction of forearm and palm respectively. The bones had certainly not been struck to increase the resistance. It could only be supposed that the bullet causing this injury must have been revolving around its transverse axis as it passed. This resembles the revolution of pieces of high velocity shell which must be assumed to take place in the many cases in which a quite small entry wound exists, together with a very extensive cavity formed by laceration of the soft parts within the limb.

A remarkable case offering absolute proof of the retention of sufficient heat by a spent bullet to burn the surface of the skin is worthy of mention, since it is the only instance which I have ever seen. A man under rifle fire was twice hit in the legs, and when on the ground thought he felt hot blood trickling over the front of his abdomen. He put his hand under his shirt and found a rifle bullet lying loose. Two days after five separate exact impresses of the bullet were to be seen on the abdominal wall, still bright red, and over two vesication had occurred; thus a burn of the second degree had been produced.

---

[1] THE LANCET, Oct. 10th (p. 905) and 24th (p. 1005), 1914.

The multiple wounds produced by the continuous discharge of the machine guns were referred to in a previous note. A remarkable instance is at present under treatment; the five wounds passing transversely from before backwards are in a vertical line on the left side of the head and neck; the highest produced a gutter fracture of the left parietal region (which will possibly cause the death of the patient), the second struck the scalp below, a third bullet entered at the angle of the mandible and remained lodged over the surface of the bone, a fourth struck the mastoid process, and the fifth entered the root of the neck, wounding the carotid and jugular, between which vessels an arterio-venous communication of the aneurysmal varix type now exists.

Gangrenous Cellulitis.

The presumption expressed in a former note that the occurrence of gangrenous cellulitis might become rare with the establishment of more rapid means of transport has, unhappily, not been substantiated. A considerable number of these cases are still met with both at the clearing hospitals as well as at the medical base.

It has also proved that this condition may develop as the result of a simple rifle bullet wound, and when this is the case the absence of the safety vent afforded by the larger shell wounds may render the extension of the infection a still more rapid process. With regard to the influence of delay in transport on the development of gangrenous cellulitis, this affects only the extent to which the process may have reached when the patient comes under treatment, and can hardly be assumed to favour its actual origination. Experience of the same disease in civil practice needs only to be recalled to emphasise the rapidity with which the infection gains ground and the unlikelihood that any local antiseptic treatment could effectually cut it short.

The influence of the mechanical factor in favouring the spread of the process is well illustrated by the fact that while it spreads readily from wounds involving the deep planes of the limbs, the condition is not observed to develop in wounds of the thoracic parietes, of the abdominal wall, the neck or the scalp. In the latter cases the wounds afford sufficient vent to prevent the development of the tension which favours the extension of the process; again, it is clear that many large gaping wounds are affected locally by the same organism, gas bubbling up in large quantity from their depths while no progressive extension occurs.

Much work in the cultivation of the anaerobic organism is being done by Mr. Rowlands and Sir Almroth Wright.

The rapidity with which the condition develops does, however, vary somewhat, possibly from the degree of resistance possessed by the individual patient, sometimes, perhaps, from the fact that the infection is a mixed one, but certainly in direct proportion to the mechanical tension which exists in the affected limb, and which is usually dependent on the size and nature of the wound.

The advent is not heralded by serious general symptoms, neither the temperature nor pulse-rate rises very high, and there is little pain. The most striking features in the later progress are sleeplessness, the development of extreme anæmia, and a peculiar slackness in the tension of the pulse. The patients meanwhile take their food well, smoke cigarettes, and make little complaint.

Locally the first signs are rapidly increasing œdema, at first white, later large patches of bronzy redness of unequal depth of tint develop, while at the upper limit of the discoloured area crepitation is palpable. The bubbles of gas are often sufficiently large to raise an elevation which suggests on inspection a small varix of a vein; this is often seen in the areolar tissue over Scarpa's triangle. The glands of the axilla or groin enlarge early, but they are hard, not very tender, and never reach a large size or suppurate.

After two or three days the portion of the limb distal to the wound becomes cold, pulseless, and gangrenous. The distal gangrene is of the arterial type. The limb in cases which survive long enough mummifies, and a very sharp line of demarcation develops. Some of these limbs are intensely black in colour.

Only a small proportion of the cases present the typical tense limb with a "marbled" surface, but these are occasionally seen; in one which came under my notice the tense swelling not only involved the whole lower extremity and the trunk as high up as the angle of the scapula, but the penis and scrotum also attained a huge size. In a more frequent variety the proximal portion of the limb acquires a peculiarly soft boggy feeling with deep crepitation, especially along the vascular clefts; these are instances of a mixed infection, commonly with streptococcus. This seems evident, as in many cases which improve the anaerobic organism dies out and streptococcus cultivations only can be obtained from the wounds. The active hæmolytic change produced by the organisms is not only evidenced by the staining of the surface of the limbs, but also by the colour of the serous exudation from incisions made to relieve tension which are of a brilliant orange tint.

It is a very unusual surgical experience to have so frequently the opportunity of palpating surgical areolar emphysema as we have here. In one hospital the sign may be elicited successively in cases of wound of the trachea or lung, in cases of injury to the colon, and in limbs the subjects of emphysematous gangrene.

Treatment of Gangrene.

With regard to the treatment of the cases of gangrene no satisfactory method has been discovered. There is no doubt that multiple incisions made at the limit of advance of the process check it and bring it to a standstill, and some benefit has been claimed from the method of injecting hydrogen peroxide in the same region, although I have seen little to support the opinion myself. The adoption of this method, however, lands the surgeon in a serious difficulty, since in spite of the arrest of the gangrenous process the perished limb persists as a source of septicæmia, hectic develops, anæmia becomes extreme, and the patient succumbs before the opportunity for the performance of a secondary amputation arrives. A considerable difference exists in this respect, however, between the treatment of the upper and lower extremities. In the former a considerable proportion of the cases survive, while of the latter the large majority of the patients die from shock and septicæmia during the next 36 hours if the amputation needs to be made through the thigh. In either case the only chance of securing a success lies in fashioning short flaps and leaving the stump completely open, for in all suppuration or an extension of the gangrenous process follows if the stumps are closed.

It is of interest to note that we are meeting with other forms of gangrene, the purely mechanical due to the degree of injury to the soft parts, embolic arterial gangrene following injury to the great vessels, and already some instances of frost bite of the toes.

ALCOHOL AND THE WAR.

A conference took place at Caxton Hall, Westminster, on Thursday, Nov. 12th, under the chairmanship of the Archbishop of Canterbury, the object of the conference being to consider the problem of "Alcohol in its Relation to the War."

The Archbishop of Canterbury opened the meeting by referring in some detail to the reports which had been received of intemperance both among soldiers in training and also among their dependents. He did not feel, he said, that the blame attached so much to those who had fallen into this temptation, but to those who had placed temptation in their way or who failed to hold out the helping hand to those who particularly needed help. He believed that the situation could best be met by the wide adoption of a pledge of total abstinence for the period of the war, a view he had already expressed in a letter to the *Times*. By this act of self-denial those at home could show their sympathy with those at the front.

The first resolution recognised that as a result of the war there had been a grave increase of intemperance and pledged the members of the conference strongly to support Lord Kitchener's appeal for national help in this situation. Lord Roberts had signified his intention of being present and had been invited to propose a resolution to this effect, but he wrote a letter explaining that as he was going to France to see the Indian troops he could not be present. His place was therefore taken by Sir Clifford Allbutt.

Sir Clifford Allbutt bore testimony to the good behaviour of the troops quartered at Cambridge; at the same time he fully recognised the extent of the evil. He stated that science had made it clear that healthy people are all as well, or better, without alcohol as with it, and referred to the theory, wrongly included under the head of Darwinism, that the evil would settle itself when those who have cravings for alcohol have been eliminated. He contended that the problem of to-day was not so much one affecting individuals as communities. If we wanted to see a strong community we must get rid of class distinctions and seek to help one another, and especially the dependents of those who were serving their country in the war. The public-houses had unfortunately been for many the only place for social gathering, and it was most important that other attractions should be provided.

Cardinal Bourne, Archbishop of Westminster, in seconding the resolution, fully corroborated the Archbishop of Canterbury's statement as to the dangers of the moment in relation to alcohol. Emotions, he said, were gravely excited where men were leaving home to go to posts of peril, while those who were left behind were in distress and anxiety. He advocated further restrictions in the hours of opening public-houses.

Sir Thomas Barlow then proposed the second resolution, which recommended the general adoption of the suggestion that people of all classes should join in a pledge of total abstinence during the continuance of the war. Seeing that the resolution proposed a pledge of total abstinence for men in the services and civilians at home, he dealt with a difficulty felt by some as to the possibility of pure water being obtained by the troops. He said that, having carefully inquired into this subject, he was assured that under the excellent sanitary system initiated by the Army Medical Department there would be no difficulty of this kind. He referred to the occurrence of sexual disease, nine-tenths of the cases of which were believed to be mainly the result of alcoholism, saying that if we want to send our young soldiers across the Channel without any disability we must stop alcoholism. He had been told that when the German regiments first started out their behaviour was all that could be desired, but when they had been in the wine cellars lust, cruelty, and pillaging took place. He desired to emphasise the fact that the evil was an insidious one, and must be resolutely met by getting public authorities to do their duty, by providing other attractions and promoting a true sense of brotherhood, and particularly by renouncing the use of alcohol for the sake of others.

The Rev. J. Clifford, D.D., seconded the motion in an eloquent speech, pointing out how many of the troops were already total abstainers, including a very large proportion of the Indian troops.

Major Leonard Darwin proposed the third resolution, which stated that "immediate steps would be taken in every locality to secure that proper provision be made for the supply of suitable places of recreation and refreshment both for men and for women, where there would be no temptations to drink." He also urged the carrying into effect by local authorities of the Temporary Restriction Act, 1914.

A fourth resolution determined that a manifesto should be drawn up embodying the principal resolutions, and that this should be sent to Lord Mayors and mayors, urging them to take the lead in carrying out the proposals.

All the resolutions were carried unanimously.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Meeting of Council.

An ordinary meeting of the Council was held on Nov. 12th, Sir W. Watson Cheyne, the President, being in the chair.

The Secretary reported the death on Nov. 8th of Mr. Charles Barrett Lockwood, member of the Council. It was resolved to send a vote of condolence to his family.

It was resolved to grant diplomas of Membership to 67 successful candidates.

On the recommendation of the finance committee it was resolved to make a donation of 200 guineas to the National Relief Fund.

It was resolved to grant a pension to Mr. William Pearson.

Sir Frederic Eve was appointed a member of the committee of management in the vacancy occasioned by the retirement of Sir W. Watson Cheyne.

It was resolved to restore to the Membership of the College a Member who had been removed.

A letter was received from Lady Howse thanking the Council for their resolution of sympathy on the death of Sir Henry G. Howse.

The President reported that the Bradshaw lecture would be delivered by Sir Frederic Eve on Tuesday, Dec. 15th, at 5 P.M., and that the subject of the lecture would be Pancreatitis.

The English Conjoint Diplomas.—A recommendation from the committee of management of the Royal College of Physicians of London and the Royal College of Surgeons of England to alter the existing regulations for the admission to the Final Examination of the Conjoint Examining Board of students from recognised colonial, Indian, and foreign universities, has been approved and adopted by the councils of the two Royal Colleges. The revised regulation lays down that members of such universities who shall have passed such an examination or examinations at their Universities for the degree of Doctor or Bachelor of Medicine or Surgery as shall comprise the subjects of the First and Second Examinations of the English Conjoint Board, and who shall have completed the curriculum of medical study required by the regulations of the Board, will, two years after having passed such examinations, be eligible for admission to the Third or Final Examination for the L.R.C.P. and M.R.C.S. diplomas.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon James William Wilcocks Stanton has been placed on the Retired List.

The following appointments have been notified:—Staff-Surgeon: G. L. Buckeridge to the *Halcyon*. Temporary Surgeons: E. G. Fisher to the *Colleen*, additional, for Haulbowline Hospital Yard; and E. I. Parry to the *Indus V*.

The undermentioned have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet: Thomas Creaser and Harry Marmaduke Langdale.

The undermentioned have been entered as Surgeons for temporary service in His Majesty's Fleet: Harry Oliver Blanford, George Muir Fraser, David Alexander Henderson, Eric Ambrose Linell, Matthew Neilson, John Pratt, Alfred George Sworn, Arthur Hyde Wear, John Philip Walker, Joseph Henry Bennett, and Clement Wheeler Wheeler-Bennett.

ADMINISTRATIVE SERVICES, ROYAL NAVAL DIVISION.

Fleet-Surgeon Arthur Gaskell, R.N., to be Assistant Director of Medical Services (dated Sept. 22nd). Captain F. Casement, R.A.M.C., to be Deputy Assistant Director of Medical Services with the temporary rank of Captain in the Royal Marines (dated Aug. 21st).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Herbert E. Cree is retained on the Active List under the provisions of Article 120 of the Royal Warrant for Pay and Promotion, 1913, and to be supernumerary (dated Nov. 27th).

George Seaton Buchanan is granted temporarily the honorary rank of Lieutenant-Colonel (dated Nov. 17th).

Major Robert J. Blackham, C.I.E., is seconded for service under the Government of India (dated Nov. 4th).

The undermentioned to be temporary Captains:—Dated Nov. 1st: Edward Kenneth Martin, Alfred Edward Johnson, and Robert Davies-Colley.

Temporary Lieutenant F. S. Brereton, late Captain, Royal Army Medical Corps, to be temporary Captain (dated Nov. 13th).

The undermentioned to be temporary Lieutenants: Dated Sept. 30th: George Leonard Grant. Dated Oct. 22nd: Trevor Richard Snelling, Richard Charles, Henry Charles Cadell Rennie, and Charles John Edgar. Dated Oct. 23rd: Arthur de Winton Snowden. Dated Oct. 24th: Roland Ravenscroft Wettenhall, Michael Joseph Kelly, Arthur Seal Blackwell, Evan William Griffith, Arthur Gibson Leitch, David Neilson Knox, William Wright Mackarell, John Boyd Orr, James Gray Duncanson, Maurice Patrick Scanlon, and Ernest Alfred Tozer. Dated Oct. 25th: Robert Williams Michell and Charles McMoran Wilson. Dated Oct. 26th: John MacInnes. Dated Oct. 27th: Warren Meade. Dated Oct. 28th: Thomas Henry Agnew and Martin Wentworth Littlewood. Oct. 29th: David Winthrop Woodruff and Robert Lee Brown. Dated Oct. 31st: John Burd Wood. Dated Nov. 1st: James Wilson Richardson, William Nicholas Alexander, Archibald Francis Wright, Horace Arthur Cutler, Arthur Geden Wilkinson, Hugh Young Riddell, Edward Francis Palgrave, Richard Picton Rosser, Charles Edgar Holton Smith, David James Melville Legge, William Robert Addison Coates, Reginald James Rogers, Herbert Lincoln Hatch, Stephen Barry Walsh, James Kilian Clarke, George Ernest Vilvandré, Peter Drummond, David John Evans, and William Anketell Leeper Dunlop. Dated Nov. 2nd: Charles Lester Graham, Charles Derwent Pye-Smith, Harold Mowat, William Alexander Hislop, John Norman Glaister, John Alexander, Francis Kenneth Kerr, Alexander Gordon Gilchrist, Thomas Boston Johnstone, Charles Murchison Bernays, Charles Ashley Flintoff, Ralph Stuart Renton, Lawson Cairns, Richard Bevan Llewellyn, Edward Daniel Parsons, Robert Crothers, Arnold Leeming, Peter Hamilton Robertson, Percy Gonville Lock, Laurence William Pole, William Tregenza, and Robert Thomson. Dated Nov. 3rd: Octavius Studdert Maunsell.

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers:—Lieutenants to be Captains: Dated July 29th: Percival Sandys Connellan, John Alexander Sinton, Eric Edward Doyle, Cyril Macdonald Plumptre, Archibald Wallace Duncan, Henry Lewis Barker, and Edward Austen Penny.

The King has approved the retirement of Lieutenant-Colonel George Yeates Cobb Hunter (dated Oct. 25th.)

The services of Lieutenant-Colonel S. E. Prall have been placed temporarily at the disposal of the Government of India. Captain M. A. Nicholson has been appointed to act as Civil Surgeon, Jacobabad, in addition to his own duties. Captain Robson has been posted to the Punjab. Major McConaghy has been posted to Bhopal as Agency Surgeon. Major Wilson has been posted as Medical Officer to the Mewar Bhil Corps. Major Hugo has been posted to Kashmir as Residency Surgeon.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Home Counties Field Ambulance:—To be Lieutenants: James Evan Turle and Charles Hebden Gregory.

4th London Field Ambulance: To be Captains: George Earnest Nash and Lieutenant Alfred J. Williamson.

5th London Field Ambulance:—To be Captains: Sydney Clark and Charles Ernest Whitehead.

6th London Field Ambulance: Francis Rowland to be Captain.

1st North Midland Field Ambulance: To be Lieutenants: Ronald Briers Berry, Matthew Thomas Ascough, and John William Thomson.

2nd North Midland Field Ambulance: Captain Richard M. West to be Major.

3rd North Midland Field Ambulance: To be Lieutenants: Charles Christopher Grummitt and Wilfrid Anthony Legh Jackson.

3rd Northern General Hospital: Frank Arthur Hepworth to be Captain.

2nd West Riding Field Ambulance: Charles Nixon Smith to be Lieutenant.

1st London (City of London) Sanitary Company: Martin Priest to be Lieutenant.

1st Welsh Field Ambulance: Major Evelyn J. R. Evatt to be Lieutenant-Colonel (temporary).

3rd Welsh Field Ambulance: Major Andrew R. Wilson, from Attached to Units other than Medical Units, to be Lieutenant-Colonel.

1st London (City of London) General Hospital:—To be Captains: Thomas Jeeves Horder and Conrad Meredith Hinds Howell.

3rd London General Hospital: Lieutenant-Colonel Sir Rickman J. Godlee, Bart., K.C.V.O., resigns his commission. Major Bilton Pollard resigns his commission on account of ill-health. Major Sir Alfred P. Gould, K.C.V.O., to be Lieutenant-Colonel. Captain James E. Lane to be Major (to remain seconded). Captain Arthur F. Voelcker to be Major. Captain Sir John Bland-Sutton to be Major. Richard Robert Cruise to be Captain.

Notts and Derby Mounted Brigade Field Ambulance: Major Alexander R. Tweedie to be Lieutenant-Colonel. Captain Walter H. Fisher to be Major. Douglas John Marr to be Lieutenant.

1st South-Western Mounted Brigade Field Ambulance: Major Thomas H. Haydon to be Lieutenant-Colonel. Captain Alexander W. French to be Major.

1st Southern General Hospital: Major James T. J. Morrison is seconded.

3rd West Riding Brigade: Surgeon-Captain Archibald W. Cuff to be Surgeon-Major.

2nd East Lancashire Field Ambulance: Captain Alexander Callam is restored to the establishment.

2nd London Sanitary Company: James Clayton to be Lieutenant.

2nd East Anglian Field Ambulance: James Simson to be Lieutenant.

2nd Home Counties Field Ambulance: Frank Scroggie to be Lieutenant.

2nd Lowland Field Ambulance: James Wilson Burton to be Lieutenant.

3rd West Riding Field Ambulance: Oswald Frank Buxton to be Quartermaster, with the honorary rank of Lieutenant.

2nd Northern General Hospital: Douglas Seaton to be Captain.

2nd Scottish General Hospital: Captain David J. Graham to be Major.

4th Scottish General Hospital: James Robertson Riddell to be Captain.

Attached to Units other than Medical Units.—Lieutenant-Colonel John Macfarlane Cadell, retired pay (late Indian Medical Service), to be Major. Captain Haldinstein D. Davis is seconded. To be Captains: Henry William Williams, late Captain, Royal Army Medical Corps (Territorial Force), Lieutenant Robert N. Wallace, and Lieutenant George D. Collen. To be Lieutenants: John Leslie Green, Herbert Robertson, Philip Henry George Gosse, George Jackson Wilson, Wilson Howard Morrison, Henry Edward Fox, and Percival Thomas Rutherford (late Second Lieutenant, 4th London (Howitzer) Brigade, Royal Field Artillery).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Captain Frederick W. Sydenham, from Attached to Units other than Medical Units, to be Captain.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8083 births and 4517 deaths were registered during the week ended Saturday, Nov. 14th. The annual rate of mortality in these towns, which had been 13·8, 13·5, and 13·4 per 1000 in the three preceding weeks, further fell in the week under notice to 13·0 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 13·5, against 14·0 per 1000 in the metropolis. Among the several towns the death-rate last week ranged from 2·7 in Great Yarmouth, 3·0 in Carlisle, 5·2 in Wimbledon, 6·6 in Gillingham and in Eastbourne, and 6·7 in Devonport, to 17·6 in Blackpool, 17·8 in Merthyr Tydfil, 18·6 in Huddersfield, 22·3 in Newcastle-on-Tyne, and 22·5 in Liverpool.

The 4517 deaths from all causes were 147 fewer than the number in the previous week, and included 454 which were referred to the principal epidemic diseases, against 472 and 497 in the two preceding weeks. Of these 454 deaths, 167 resulted from measles, 131 from infantile diarrhœal diseases, 58 from diphtheria, 42 from scarlet fever, 39 from whooping-cough, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3, or 0·1 per 1000 less than that recorded in each of the two preceding weeks. The deaths attributed to measles, which had increased from 67 to 146 in the four preceding weeks, further rose to 167 last week, which was the highest number of deaths from this cause recorded in any week of this year; the highest death-rates from this disease were 1·4 in Plymouth and in Oldham, 1·5 in Edmonton, 1·9 in Huddersfield, 2·0 in Grimsby and in Wakefield, 2·2 in Gateshead, 3·4 in Wigan, and 4·6 in Newcastle-on-Tyne. The deaths of infants (under 2 years), which had steadily declined from 1223 to 169 in the eight preceding weeks, further fell to 131 last week, and included 36 in London, 13 in Liverpool, 11 in Manchester, 5 in Birmingham, and 4 each in Salford, Sunderland, and Rhondda. The fatal cases of diphtheria, which had been 79, 61, and 93 in the three preceding weeks, declined to 58 last week, of which 12 occurred in London 4 each in Liverpool, Manchester, and Middlesbrough, and 3 each in Stoke-on-Trent and Cardiff. The deaths attributed to scarlet fever, which had been 37, 38, and 34 in the three preceding weeks, rose to 42 last week, and included 8 in London, 6 in Manchester, 5 in Liverpool, and 2 each in Bristol, Oldham, Preston, Middlesbrough, and Cardiff. The deaths referred to whooping-cough, which had been 35, 32, and 38 in the three preceding weeks, were 39 last week, of which 11 were registered in London, 3 each in Nottingham and Liverpool, and 2 each in Manchester, Salford, South Shields, and Newcastle-on-Tyne. The fatal cases of enteric fever, which had been 19, 14, and 17 in the three preceding weeks, were again 17 last week, and included 3 in London and 2 each in Bradford and South Shields.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 4769 in the 12 preceding weeks, had further risen to 4976 on Saturday last; 751 new cases were admitted during the week, against 657, 598, and 690 in the three preceding weeks. These hospitals also contained on Saturday last 1602 cases of diphtheria, 72 of enteric fever, 62 of measles, and 57 of whooping-cough, but not one of small-pox. The 1153 deaths from all causes in London were 49 fewer than in the previous week, and corresponded to an annual death-rate of 13·3 per 1000. The deaths referred to diseases of the respiratory system, which had been 191, 197, and 193 in the three preceding weeks, further declined to 181 in the week under notice, and were 23 below the number recorded in the corresponding week of last year.

Of the 4517 deaths from all causes in the 97 towns, 194 resulted from different forms of violence and 370 were the subject of coroners' inquests, while 1329 occurred in public institutions. The causes of 36, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Nottingham, and in 75 other smaller towns. Of the 36 uncertified causes of death, 7 each were registered in Birmingham and Liverpool, 4 in Stoke-on-Trent, 3 in London, and 2 each in Bury, Sheffield, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1071 births and 668 deaths were registered during the week ended Saturday, Nov. 14th. The annual rate of mortality in these towns, which had been 15·0, 14·6, and 15·8 per 1000 in the three preceding weeks, declined to 15·2 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 15·2, against 13·5 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 5·0 in Motherwell, 6·3 in Ayr, and 8·8 in Kilmarnock, to 18·6 in Dundee, 18·7 in Greenock, and 18·9 in Hamilton.

The 668 deaths from all causes were 28 fewer than the number in the previous week, and included 50 which were referred to the principal epidemic diseases, against 78 and 79 in the two preceding weeks. Of these 50 deaths, 20 resulted from infantile diarrhœal diseases, 8 from scarlet fever, 7 from diphtheria, 7 from whooping-cough, 5 from enteric fever, and 3 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·1, against 1·3 per 1000 in the 97 large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 31, 26, and 24 in the three preceding weeks, further declined to 20 last week, of which 7 were recorded in Glasgow, 4 in Edinburgh, and 2 each in Dundee, Paisley, and Coatbridge. The deaths referred to scarlet fever, which had been 16, 14, and 17 in the three preceding weeks, fell to 8 last week, and comprised 5 in Glasgow, 2 in Aberdeen, and 1 in Edinburgh. The fatal cases of whooping-cough, which had been 9, 14, and 12 in the three preceding weeks, fell to 7 last week, of which 6 occurred in Glasgow and 1 in Hamilton. The deaths attributed to diphtheria, which had been 19, 16, and 18 in the three preceding weeks, fell to 7 last week, and included 3 in Glasgow and 2 in Dundee. The 5 deaths referred to enteric fever were equal to the average in the earlier weeks of the quarter, but showed no excess in any of the towns. The 3 fatal cases of measles, of which 2 were recorded in Glasgow and 1 in Dundee, were also equal to the average in the earlier weeks of the quarter. In addition to the deaths from the above epidemic diseases, a fatal case of typhus was registered in Dundee.

The deaths referred to diseases of the respiratory system, which had steadily increased from 62 to 104 in the eight preceding weeks, further rose to 111 in the week under notice; 32 deaths resulted from different forms of violence, against 17 and 30 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 514 births and 408 deaths were registered during the week ended Saturday, Nov. 14th. The annual rate of mortality in these towns, which had been 15·8, 15·2, and 18·2 per 1000 in the three preceding weeks, fell to 17·7 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 16·4, against corresponding rates of 13·5 and 15·2 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 18·1 in Dublin (against 13·3 in London and 15·3 in Glasgow), 16·6 in Belfast, 15·6 in Cork, 20·3 in Londonderry, 16·2 in Limerick, and 26·6 in Waterford, while in the 21 smaller towns the mean death-rate was 18·1 per 1000.

The 408 deaths from all causes were 12 fewer than the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 51 and 48 in the two preceding weeks. Of these 40 deaths, 14 resulted from scarlet fever, 10 from infantile diarrhœal diseases, 9 from measles, 3 from diphtheria, 2 from enteric fever, and 2 from whooping-cough, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·7, against corresponding rates of 1·3 and 1·1 per 1000 in the English and Scotch towns respectively. The deaths attributed to scarlet fever, which had been 5, 12, and 6 in the three preceding weeks, rose to 14 last week, and comprised 8 in Belfast, 5 in Waterford, and 1 in Dublin. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 21, 19, and 21 in the three preceding weeks, declined to 10 last week, of which 4 occurred in Dublin and 4 in Belfast. The fatal cases of measles, which had been 7, 7, and 11 in the three preceding weeks, fell to 9 last week, and included 7 in Belfast. The 3 deaths attributed to diphtheria, comprising 2 in Kilkenny and 1 in Cork, were equal to the average in the two preceding weeks. The 2 deaths from whooping-cough were recorded in Belfast, and those from enteric fever in Dublin and Ballymena. In addition to the above, a fatal case of typhus was registered in Dublin.

The deaths referred to diseases of the respiratory system, which had been 60, 61, and 86 in the three preceding weeks, fell to 67 in the week under notice. Of the 408 deaths from all causes, 144, or 35 per cent., occurred in public institutions, and 4 resulted from various forms of violence. The causes of 17, or 4·2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Medical Life in Paris To-day.

NOTWITHSTANDING the preoccupations and horrors of war medical life in Paris has resumed its course in all the scientific societies. Naturally, most of the communications concern themselves with the all-absorbing topic of the hour. At the Académie de Médecine, M. Rémond, of Toulouse, has recommended the use of a camphorated saline, obtained by adding camphor (which dissolves in the proportion of 20 centigrammes in 100 cubic centimetres) to any isotonic serum. This camphorated serum, given intravenously, brings about rapid resolution of the morbid conditions in pneumonia and bronchopneumonia. It also favourably influences staphylococcal and streptococcal infections, and seems to offer all the advantages of camphorated oil without any of its disadvantages. M. Fernet recommends the use of two pairs of gloves or socks to overcome cold; cotton gloves or socks are recommended to be worn next the skin, and covered externally with woollen ones. M. Demmler has forwarded a communication of particular interest at the present time, when so many of the wounded are affected with tetanus. Recalling Dr. Verneuil's advocacy of chloral in 20 to 25 gramme daily doses, M. Demmler recommends its administration in a dose of 6 grammes every six hours until torpor is produced, which suppresses the hyperexcitability of tetanus. M. Capitan, who read this communication to the Academy, added that he owed a complete success in a particularly grave case to this method. The Société de Chirurgie received a communication from Dr. Quénu on the treatment of gangrenous wounds in warfare by opening up of the wound and sterilisation by hot air. As immediate primary opening up was a matter for the medical service at the front, M. Quénu's observations dealt only with delayed and secondary incision. After free incision a minute disinfection of the ragged parts of the wound is called for. Spraying and irrigation with pure oxygenated water are very useful for that purpose. This disinfection suffices for small superficial sloughing, but for cases in which the gangrene invades muscular masses and extends deeply recourse must be had to sterilisation of the wound by hot air up to 500° or 600° C. with Gaiffe's apparatus. It is important to cleanse the smallest recesses without dread of destroying muscles. The large vascular and nerve trunks should be avoided. These measures are succeeded on the following days by irrigation with oxygenated water. This method seems to M. Quénu to be the best treatment for partial gangrene and to afford the greatest protection against its spreading and the transformation of a partial into a complete gangrene. M. Toussaint reported two cases in which he showed that Michel's clamps appeared to have brought on phlegmonous complications, which receded after the removal of the clamps and drainage of the wounds. Dr. Paul Thierry recommended in serious cases of septicæmia among the wounded in war the use of hypodermic injections of from 1 to 2 centigrammes of pilocarpine repeated daily. The profuse sweating occasioned, in conjunction with a free ingestion of abundant fluids, causes a veritable lavage of the blood, and removes the toxins from the blood without injuring the red corpuscles. This procedure may give excellent results even in desperate cases.

The Opening of the Winter Session.

At this time of the year the streets of Paris are usually invaded, so to speak, with a cloud of white posters announcing the reopening of the various courses of higher instruction. This year these posters present an extraordinary character, stating, as they mostly do, that such-and-such a professor will be replaced by a colleague, since he has been called up to serve with his regiment. Naturally, the Faculty of Medicine is one of those most affected by this calling up of its professors for military service. Though the courses for the first- and second-year students will continue under almost normal conditions, practically all the other courses have been postponed to the summer session. Courses of internal and external pathology, however, will be held during the winter session, and the clinics will remain open to students. There has been considerable misgiving that the continuance of the regular courses may give an unfair advantage to students exempt from military service or not yet called up, to the prejudice of those who are on service. The Ministry of Public Instruction has accordingly made an announcement which should dissipate these fears. A series of measures have been taken to safeguard the rights of those students who are fighting for their country—cumulative inscriptions, special examinations and courses, and adjournment of the *concours* until the termination of hostilities.

Foreign Bodies in Military Surgery.

At a recent meeting of the Académie des Sciences Professor Lippmann drew attention to the electromagnetic balance devised by the well-known electrician, M. Hughes, which discloses the situation of a metallic substance (e.g., a coin, bullet, &c.) in the body. This apparatus is the more suitable for military use in that it is simple and can be easily constructed at small expense. It consists of an electric battery, an interrupter, and two small induction coils communicating with a telephone, which rings whenever one of the coils is brought into contact with a metallic substance. If the latter is magnetic, as, for instance, a splinter from a shell or a German bullet, the effect is intensified. This apparatus is intended to be of service in searching for bullets wherever an X ray apparatus is not available, and is, of course, an adaptation of an old-fashioned idea.

Right to Practise for Refugee Belgian Doctors.

The Académie de Médecine has decided to seek on behalf of refugee Belgian medical men the right to exercise their profession in those localities—numerous enough just now—which have been deprived partly or altogether of medical aid. Also at the request of M. Borel, director of the Second Maritime Sanitary Area (*circonscription*), the Minister of the Interior has authorised the appointment of Belgian doctors of medicine as ships' surgeons in the French mercantile marine during the continuance of the war.

The Treatment of Captured Medical Officers.

The Société Médicale des Hôpitaux, acting on private information, occupied itself at its last meeting, together with the surgeons, accoucheurs, and specialists who wished to take part, with the fate of their prisoner *confrères*. It seems that some of them, being captured with the troops to which they were attached or the ambulances with which they served, are being treated as prisoners of war, in defiance of the regulations of the Geneva Convention, and that many are interned in camps, fortresses, and barracks without any outlet for their professional services; whereas all being furnished with the regulation brassards should have been liberated. To remedy this condition the Société Médicale des Hôpitaux has directed its secretary to address a letter to the President of the Geneva Red Cross, informing him of this regrettable occurrence, and calling on him to investigate its truth.

A New Chair at the Paris Faculty of Medicine.

A chair in the hygiene and clinical medicine of infancy has been established at the University of Paris. Dr. Marfan, professor of therapeutics in that faculty, has been nominated, at his own request, to the new chair, dating from Nov. 1st, 1914.

Nov. 16th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Italian Army Medical Service.

Surgeon Captain Mendes publishes in a recent number of the *Policlinico* a long article upon this subject which is naturally of interest in Italy where there are already nearly a million men under arms. A short account will show the general similarity in the arrangements of both Italian and British armies. To each regiment of the line, Bersaglieri or Guards, seven regimental medical officers are assigned—a captain in charge of the whole regiment, and two lieutenants to each of the three battalions of which the regiment is composed. In addition there are 6 corporals of the medical corps and 48 orderlies, or 2 corporals and 16 orderlies to each battalion. In action the regimental medical officers are responsible for the regimental dressing station, which has supplies sufficient for dealing with 300 to 350 wounded. From here the wounded pass to the "sezioni di sanità," or divisional ambulances. Each of these is divided into two equal sections. A major is in command of the whole, with 2 captains, 4 lieutenants, 8 corporals, 17 nursing orderlies, and 195 stretcher-bearers, besides the personnel of the transport. The equipment is either carried by mules or in two special wagons containing the technical outfit, eight ambulance wagons, and six ordinary regimental carts. It is provided with two tents, 7 by 7 metres, and 92 stretchers. Each army corps has one "sezione di sanità" to each of its divisions, and an additional one for its reserve troops. The next line is formed by the field hospital, transported by wagons or mules and containing 50 beds. It is under the command of a captain, with two lieutenants, a clerk, a dispenser, a priest, and a staff of 30 men. During action this small field hospital is expected to advance and take up a position near its corresponding divisional ambulance. It is provided with at least four tents, of which two are 9 by 11 metres and two 7 by 7 metres. There is one of these small field hospitals to each division. Behind these come the field hospitals of 100 or 200 beds, forming the first units of the second line, and under the orders of the general in command of the army. Twenty of these field hospitals are allotted to each army. Their staff is proportionally on the same scale as the smaller field hospitals. For the transport of the wounded to the base Italy has been supplied with excellent hospital trains by the "Croce Rossa." Each of these will take 200 cases on stretcher beds. The staff is composed of four doctors and 40 assistants. The equipment is that of a hospital, so that both surgical and medical cases can be dealt with, and the journey be continued for days without injury or inconvenience to the patients. Besides these the Army Medical Department have trains which are convertible for use for the transport of the wounded. Each of these consists of 35 covered goods vans furnished with supports and hooks to take either two or three tiers of stretchers, making accommodation available for either 280 or 420 wounded. Each train has a captain of the Army Medical Corps, three lieutenants, and 40 orderlies. Four of these trains are at the disposal of each army.

The Effect of Alcohol upon the Mental Processes of Young People.

L'Igiene della Scuola refers to some interesting experiments which Signorina Sertoli, a schoolmistress, has carried out upon the influence of small quantities of alcohol on the mental processes of young people. Her subjects were a girl aged 10 and two boys aged 14 and 16 years respectively. Their normal capacity as regards attention and memory was first determined and the experiments were made two months later. Half an hour before examining a small quantity of marsala, containing 14 per cent. of alcohol, was administered, the amount varying with the age of the subject, and increasing slightly in successive experiments. The conclusions arrived at were: 1. Alcohol in small quantities produces a psychical excitation which rapidly reaches its maximum and slowly declines. 2. A slight alcoholic excitation renders the process of attention quicker, more intense, and more oscillating. 3. As regards memory, it makes the process of fixation more rapid and clear, but the conservation of the memory-contents is less resistant. At the same time, it is a transitory cause of the rise of subconscious memories to the level of consciousness. 4. Alcohol causes the lowering or disappearance of certain moral sentiments, especially those which tend to restrain human activities. This effect varies with the temperament of the subject, being greatest in the emotional and least in the phlegmatic.

Nov. 14th.

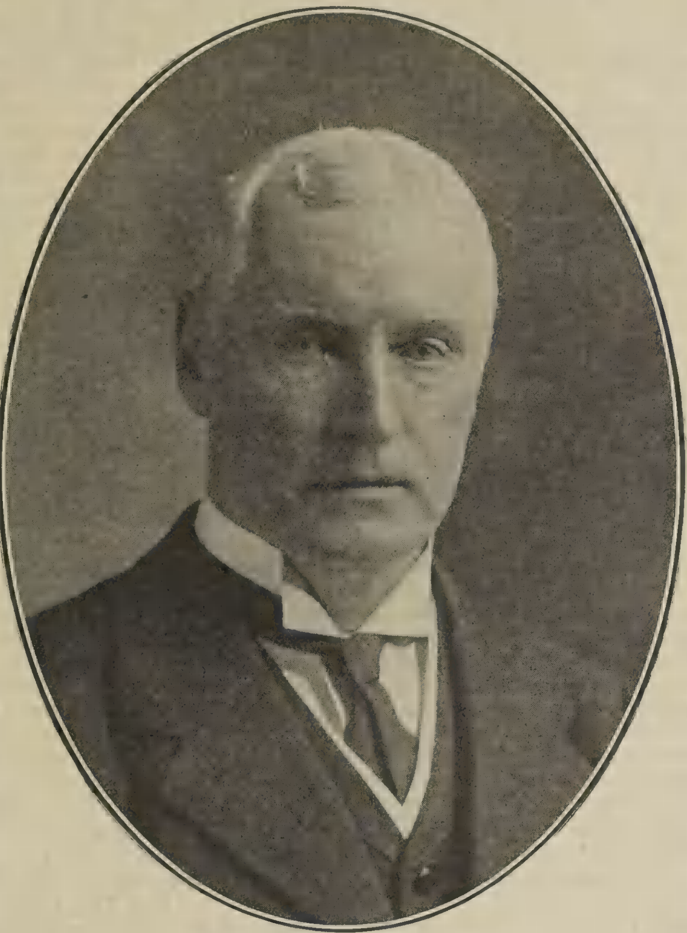
THE BENGAL MEDICAL COUNCIL.—The constitution of the Bengal Council of Medical Registration is now complete, and the following medical men have been appointed members:—Surgeon-General F. A. Harris, C.S.I., M.D., I.M.S., Surgeon-General with the Government of Bengal (President); Lieutenant-Colonel W. J. Buchanan, C.I.E., M.D., I.M.S., Inspector-General of Prisons, Bengal; Lieutenant-Colonel F. O'Kinealy, I.M.S., surgeon superintendent, Presidency General Hospital; Lieutenant-Colonel E. A. R. Newman, M.D., I.M.S.; Lieutenant-Colonel J. T. Calvert, M.B., I.M.S., Principal and Professor of Medicine, Medical College, Calcutta; Lieutenant-Colonel C. R. Stevens, F.R.C.S., I.M.S., professor of clinical and operative surgery, Medical College, Calcutta, and Surgeon to the College Hospital; Major D. McCay, M.D., I.M.S., professor of physiology, Medical College, Calcutta; Rai Upendra Nath Brahmachari Bahadur, M.D., teacher of medicine, Campbell Medical School, Calcutta; Lieutenant-Colonel A. E. Harold Brown, M.D. Durh., M.R.C.P., I.M.S. (retired); with Dr. S. P. Sarbadikari, Babu Hari Dhan Dutt, L.M. & S., Dr. Kedar Nath Das, L.M. & S., Dr. Sarat K. Mullick, and Rai Sahib Giris Chandra Bagchi.

Obituary.

CHARLES BARRETT LOCKWOOD, F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

Mr. C. B. Lockwood, the distinguished surgeon and anatomist, whose death took place on Nov. 8th at his residence, 19, Upper Berkeley-street, W., was the third son of the late George Lockwood. He was born at Stockton-on-Tees on Sept. 23rd, 1856, and was educated at Bramham School and St. Bartholomew's Hospital. He qualified M.R.C.S. Eng. in 1878, and obtained the Fellowship three years later. In 1882 he was appointed demonstrator of anatomy in the medical school of St. Bartholomew's Hospital, and held this post until 1892, when he was appointed assistant surgeon to the hospital. He was promoted to be full surgeon at the end of 1903, filling the vacancy caused by the death of Mr. W. J. Walsham, and retired from the active service of the hospital in 1912, when he was elected consulting surgeon. Mr. Lockwood's ten years' work in the anatomical department formed an important epoch in his career. He soon built up a high reputation both by his researches in anatomy and by his general teaching capabilities. At this period, though he was always rather reticent on the subject, it would appear that his life was by no means an easy one. One of his oldest friends writes, "I have seen his career from the struggling demonstrator of anatomy days to the zenith of his fame," and from this and private information it is clear that the fight for supremacy was very strenuous. In this he was not alone. Sir Henry Butlin, one of his greatest friends, passed through a similar ordeal. Both emerged from the fight with conspicuous success.



CHARLES BARRETT LOCKWOOD.

(From a photograph by Messrs. Elliott and Fry, Limited.)

In addition to his duties at St. Bartholomew's Hospital Mr. Lockwood was for some years surgeon to the Great Northern Central Hospital and consulting surgeon to the Royal General Dispensary. In 1887, 1888, and 1889, and again in 1895 he was a Hunterian professor at the Royal College of Surgeons of England, while in 1908 he was elected to the Council of the College and held this office at the time of his death. In 1904 he delivered the Lettsomian lectures before the Medical Society of London on "Aseptic Surgery in Theory and Practice," a subject which he had made peculiarly his own. Mr. Lockwood also had the distinction of having served as president of the Anatomical Society, of the Medical Society of London, and of the Harveian Society of London. A colleague sends the following intimate appreciation of Mr. Lockwood's work and character :—

"The unexpected and early death of a great surgeon must invariably come as a severe blow to those who have worked with him, more especially when the attendant circumstances are of so tragic a nature as in this case. Here is a surgeon who had spent many years of his life in combating sepsis, who had devoted his talents to the elucidation of the precepts of aseptic surgery, and who had taught on this subject to the whole world; here is such a man finally falling a victim to those very organisms against whose action he had fought so strenuous and so successful a fight. And yet the manner of his death was typical of the way in which he never spared himself when the life of a patient was at stake. Early in October he was operating on a patient for appendicular peritonitis, a disease on which Lockwood had written so insistently and thoroughly. The condition of the patient was grave and great speed of execution was demanded, and he pricked his finger when inserting almost the last stitch. He was taken ill the same night, and died five weeks later from septicæmia.

When I entered St. Bartholomew's in 1894 Willett, Butlin, and Lockwood were the three surgeons who impressed me most—Willett by reason of his ruggedness, strength of character, and honesty of purpose; Butlin on account of his teaching and interesting personality; Lockwood through his wit and his striking surgical technique. How little I thought that I should subsequently act as his assistant surgeon for many years and attend him on his deathbed. In the wards of the hospital he was beloved by his house surgeons and by his dressers. The patients seemed instinctively to know that they had a great man to deal with. His powers of observation were so keen that no malingerer ever escaped undetected. No point in the history of the case was considered too trivial, and no clinical fact was eliminated except after the most careful scientific and pathological investigation. During the nine years that he occupied the post of surgeon to the hospital three assistant surgeons served under him, each of whom considered that no task was too great if set by him.

Lockwood always expressed himself in few words, concise and dogmatic. He loved nothing better in the evenings, after the day's work was done, than that one of his friends or colleagues should drop in for a chat on surgery or fishing. When visited unexpectedly he was always to be found at work, engaged at his correspondence, writing up his cases—every case that he operated on, whether in hospital or in private, whether serious or trivial, was fully noted. Then, again, he was a serious author, his writings on 'Aseptic Surgery,' 'Hernia and Varicocele,' 'Appendicitis,' 'Carcinoma of the Breast,' &c., being accepted as standard works throughout the surgical world. During the last few weeks of his life he was fully occupied in working up the surgery of 'Movable Kidney'—delighted at being engaged in some new methods of treatment. He was always enthusiastic on his subject and always dogmatic, totally regardless of opposition, confident in his theories and practice. Of his writings, however, I have always thought that his 'Clinical Lectures' were most typical of the man—examples of his great powers of observation and attention to clinical details. He often used to tell me that he rather dreaded giving a clinical lecture. He was more nervous when talking than when carrying out the most serious operation, and it cannot be denied that his house surgeons and dressers occasionally experienced difficult afternoons. He suffered from neuritis, and certain exacerbations of this trouble led to some irritability of temper. At such periods his wit, usually humorous, became caustic. The nursing staff also suffered on these occasions, but he often said to me, 'Yes, I know they hate me, but they always come to me when they want advice and treatment.' No one could hate him in reality; such sentiments were impossible, but he was sometimes feared by those who did not know him and who did not fully appreciate his kindness of heart. To those who knew him well he was always lovable, though such a word barely expresses one's real sentiments; he was too notable a character — veneration more accurately defines one's feelings.

All his cynical traits, however, were abolished after his marriage seven years ago, and he had three children whom he adored. He remained as keen on his work, as unsparing of himself and as great a teacher, but the strain of hospital routine began to exercise some effect upon him and he retired from active hospital practice two years ago. He meditated leading a quieter life, took a house in the West of England, and there spent as much time as his private practice allowed."

Mr. Lockwood was buried at Instow, on the North Devon coast, on Nov. 12th, in the presence of a large gathering of friends. Earlier in the week a memorial service was held at the Church of St. Bartholomew the Less, close to the wards and theatres in which he had worked. He will long be remembered as a great clinical teacher and a great personality.

Correspondence.

"Audi alteram partem."

IN AID OF OUR BELGIAN COLLEAGUES.

To the Editor of THE LANCET.

SIR,—The committee whose formation has already been announced in your columns is desirous of starting an immediate attempt to help the Belgian medical practitioners and pharmacists whose plight is so movingly represented by Professor Jacobs, as the delegate from a Belgian committee having similar aims.

The committee has made all preliminary inquiries, and has come to the conclusion that the most practical step which it can take at once is the despatch to Belgium in portable form of packets of medical and pharmaceutical material. These packets will be made up by Messrs. Burroughs Wellcome and Co. in accordance with an approved list, and will be conveyed to Belgium upon advice received from the American Ambassador and Mr. L. Hoover, the Belgian Minister, the manager of Messrs. Harrods, Limited, and Major Gordon, who has already done such good work as a medium for practical assistance between this country and Belgium.

The committee has already received promises of a certain number of subscriptions which justify it in making an experimental consignment, but it appeals to the medical and pharmaceutical professions in this country for funds to enable the Belgian medical practitioners and pharmacists to carry on their work effectually so soon as military and political circumstances permit.

We appeal also for surgical instruments; many of these, though not of the latest pattern, will be extremely valuable. The following are especially required: scissors, dressing and artery forceps, scalpels, syringes, and midwifery forceps. The instruments should be sent at once to the Master of the Apothecaries Society, Apothecaries Hall, Blackfriars, London, E.C., and any small adjustments required in them will be made.

Further, we want money to help the refugee Belgian doctors and pharmacists in this country, most of whom have nothing in this world left to them.

The intention is that the work of the committee shall develop, as the conditions of Belgium permit, and that the work shall be associated with corresponding efforts in Great Britain and Ireland, in the United States and other countries which are neutrals or allies in the war.

Subscriptions should be sent to the honorary treasurer, Dr. H. A. Des Vœux, 14, Buckingham-gate, London, S.W., and cheques should be crossed Lloyds Bank, Limited.—We are, Sir, yours faithfully,

RICKMAN J. GODLEE (*Chairman*).

THOMAS BARLOW,
President of the Royal College of Physicians of London.

W. WATSON CHEYNE,
President of the Royal College of Surgeons of England.

MEREDITH TOWNSEND,
Master of the Apothecaries Society.

W. J. WOOLCOCK,
Secretary and Registrar of the Pharmaceutical Society.

H. A. DES VŒUX (*Honorary Treasurer*).

DAWSON WILLIAMS,
Editor of the "British Medical Journal."

S. SQUIRE SPRIGGE,
Editor of "The Lancet" (*Honorary Secretary*).

Nov. 18th, 1914.

THE MEDICAL PROFESSION AND RECRUITING.

To the Editor of THE LANCET.

SIR,—I venture, with your kind permission, to draw attention to one way in which our general hospitals could render assistance at the present crisis in the vitally important matter of recruiting.

At the Leicester Royal Infirmary we have recently set aside a ward of 12 beds for the radical cure of hernia, varicose veins, varicocele, hammer-toe, and other physical disabilities removable by operation responsible under present conditions for the rejection of quite a number of keen and otherwise eligible recruits. Such patients only require, individually, a short stay in hospital, and as they have all expressed their intention to reapply for enlistment on recovery, a considerable addition will be made locally to one or other branch of the service. If this were done in a systematic way in the hospitals throughout the country I think a considerable result would be achieved.

May I also take this opportunity of respectfully suggesting that some definite instruction should be given from headquarters to medical officers examining recruits not to reject on account of varicocele (except in extreme form) otherwise eligible candidates? The different practice among different medical officers leads at present to inconsistency and individual disappointment, and prevents a considerable number of healthy and active men from entering the army. It seems a pity to disqualify, on the score of varicocele, a young man leading the active, laborious life of a farm labourer who, until he applies, is unconscious of any disability.

I am, Sir, yours faithfully,

C. J. BOND,

Vice-Chairman and Hon. Consulting Surgeon to the Leicester Royal Infirmary.

Leicester, Nov. 15th, 1914.

WESSEX DIVISION OF TERRITORIAL FORCE: APPEAL FOR MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—I beg to apply for the courtesy of your columns to make an appeal to the younger medical men in the six counties of Devon, Cornwall, Somerset, Dorset, Hants, and Wilts for candidates for the medical services of the Territorial Forces of these counties.

As is probably well known, the Territorial Force throughout the country has, by Lord Kitchener's orders, been duplicated, a reserve regiment or corps being formed in each instance to take the place of the original unit, now known as the General Service Unit. This necessarily entails a doubling of the medical officers throughout the Wessex Division. We require at present at least 31 medical officers to complete the establishments of the cavalry field ambulances, divisional field ambulances, and the various regimental units of yeomanry, artillery, engineers, infantry, and Army Service Corps.

The absolute need of an efficient medical service to maintain the health, control the sanitation, and in the event of battle succour the wounded of the troops need not be enlarged on here. Without an efficient medical service the best troops speedily lose their fighting value.

I am well aware of the severe strain which is now being thrown on our profession in coping in diminished numbers with the legitimate requirements of the civil population. But in the struggle in which the nation is engaged the needs of the army, both Regular and Territorial, are paramount, and I appeal therefore with confidence for more medical recruits. The chances of active service in connexion with these commissions are at least as good as in the case of the new army. The three General Service Wessex Field Ambulances have already been for some time at the front serving with the 8th Regular Division, and were indeed among the first Territorial troops to go there.

To save unnecessary correspondence I may state here that candidates for these commissions should be of sound health and active habits, and that in the case of field ambulances, and all except infantry units, they should be able to ride. Gentlemen who have previous service will, as far as possible, be gazetted to the rank they held on resignation. The ages at which commissions can be granted have been fixed by the War Office as under: Lieutenants should not exceed 40 years; captains, 45 years; majors, 50 years; and lieutenant-colonels, 57 years.

Candidates from the young and active members of the profession are particularly called for. I shall be glad to give any further information required.

I am, Sir, yours faithfully,

H. MACKAY,

Colonel, Army Medical Service.

Headquarters, Wessex Division T.F., Exeter, Nov. 16th, 1914.

LONG AND ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In my brief note in THE LANCET of Oct. 31st I was not discussing the history of anæsthesia but referring only to Sir James Y. Simpson's relation to the subject. Long's claims are an old story, which anyone may read at length in Dr. Hugh Young's article in the Johns Hopkins Hospital Bulletin, Vol. VIII., p. 174. Everyone will, I think, agree with the following judgment of Professor Welch:—

"The honour of making the first trial of anæsthetic inhalation in surgical operations belongs to Dr. Crawford W. Long, a respected and honorable country doctor, then living in Jefferson, Jackson County, Ga., who, in March, 1842, removed painlessly a small tumour from the neck of James M. Venable, anæsthetised by ether. He seems to have performed at least eight minor surgical operations during the next four years upon patients under the influence of ether. Dr. Long is necessarily deprived of the larger honour which would have been his due had he not delayed publication of his experiments with ether until several years after the universal acceptance of surgical anæsthesia. It is also to be regretted that his published details of the mode of administering the ether and the depth of the anæsthesia are so meagre and unsatisfactory. While the accepted rule that scientific discovery dates from publication is a wise one, we need not in this instance withhold from Dr. Long the credit of independent and prior experiment and discovery, but we cannot assign to him any influence upon the historical development of our knowledge of surgical anæsthesia or any share in the introduction to the world at large of the blessings of this matchless discovery."

Surgical anæsthesia as a practical procedure dates from Oct. 16th, 1846, when William Morton, in the Massachusetts General Hospital, Boston, gave ether to Gilbert Abbott, upon whom Dr. John Collins Warren performed a painless operation.

I am, Sir, yours faithfully,
Oxford, Nov. 16th, 1914. WILLIAM OSLER.

INTRATRACHEAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In relation to Dr. R. L. Jones's account of my cases of intratracheal anæsthesia in THE LANCET of Nov. 7th, there is one point which perhaps requires a further note. In one case of excision of the tongue the patient died from pneumonia, and this would seem to show that this method of anæsthesia is therefore no safeguard against this complication. But it ought to be pointed out that the mouth was very foul owing to the fact that the ulcerating growth had extended far back. The whole tongue was removed, so that the epiglottis stood up at the back of the floor of the mouth. I never saw a case in which post-operative shock was less marked, and the patient was sitting up reading the paper the day after operation. Nevertheless, he died a week later from septic pneumonia. I believe that this is accounted for by post-operative infection and not by inhalation of blood during the operation.

I am, Sir, yours faithfully,
ERNEST W. HEY GROVES.
Richmond Hill, Clifton, Bristol, Nov. 10th, 1914.

THE WILLIAM LANGLEY MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—A year ago you were good enough to announce that my bankers (Sir Charles R. McGrigor and Co.) would receive subscriptions from members of the West African medical staff to the above fund. I now beg to state that the sum of £47 5*s.* 9*d.* was thus collected and has been transferred, with a list of subscribers, to the Bank of British West Africa, Leadenhall-street, E.C., for the credit of the main fund, which is under the control of the committee at Lagos, Nigeria.

I understand the fund will be disposed of as follows: First, a brass tablet in the colonial church at Lagos in memory of Mr. Langley. Second, a yearly gold medal to be competed for at the schools of tropical medicine.

I am, Sir, yours faithfully,
J. P. FAGAN,
Kensington, W., Nov. 15th, 1914. (Late P.M.O., N. Nigeria.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.—The prizes were distributed to the successful students on Nov. 17th by Mr. Arthur Hood, chairman of the committee of management.

THE LADY DUFFERIN FUND.—Sir Harcourt Butler presided at a meeting of the central committee of the Dufferin Fund, at Gorton Castle, Simla, on Oct. 13th. The following were present: Sir Reginald Craddock, Sir Pardey Lukis, Raja Sir Harnam Singh, Sir James Roberts, Dr. K. A. Platt (of the Women's Medical Service for India), and Mr. G. A. Hanrahan, officiating joint secretary. The central committee of the Dufferin Fund has taken over the control of the regular service of qualified medical women recently sanctioned by the Government of India. The service is now at full strength and its members are all appointed to important centres throughout India and Burma.

THE POSITION OF BELGIAN DOCTORS AND PHARMACISTS.

By PROFESSOR C. JACOBS,
OF THE UNIVERSITY OF BRUSSELS.

BELGIUM, a blood-stained and ruined country in the horrors of despair, claims the help of her friends to whom her freely consented sacrifice has brought a ray of hope in the dreadful nightmare of the past three and a half months.

I raise my voice with a feeling of intense pity on behalf of thousands of our weeping brethren in their Calvary of suffering, but it is my pride to carry out this duty to my country. The first impulse of the Belgian medical world is to make an appeal to Great Britain, whose kindness has proved itself in such unbounded measure and with such tact and generosity. The German iron fist has closed upon our country; we have to witness the endless series of crimes that are committed in all our provinces, and we have to abide in silence. All the evils of war have been thrust upon us at the same time—a useless and cruel holocaust of human lives, a decimated, despairing, and starving population, ruined homes, and, far worse than all, our children, the only hope of our country, are being mown down by want and disease.

Our doctors have not been spared; they, too, are bearing a heavy share of the general suffering, And now long weeks, nay months, of trial stand before them, during which they know that they will have to bear a terrible burden. They will have to devote themselves untiringly, giving all their care and time, and even their lives, if need be, to the cause of their country; and yet many of them, victims of a barbarian foe, are homeless, deprived of their laboratories, instruments, and their medical stores. What will become of those that still remain of our people, threatened as they are by the grim havoc of war and by contagious disease, its constant follower?

In anticipation of these inevitable consequences it has become my duty, as the spokesman of my Belgian colleagues, to appeal to the medical and pharmaceutical world that an impulse of international fraternity may come to the aid of Belgian doctors and pharmacists. Is it realised what we in Belgium have suffered and are suffering? Duty, and duty only, has bound our doctors and pharmacists to their posts in the devastated localities; some of them are carrying on their profession in the ruined remains of destroyed buildings, whereas others have to improvise at haphazard any kind of shelter for their Samaritan work. Need I describe the manner in which they sustain themselves and how they manage to nourish their wives and children?

I have witnessed such misery amongst them! Some have had to work as navvies in order to have a few pence in their pockets; others have told me that they had not seen bread for a fortnight, but had lived exclusively on potatoes. Others had a meagre bunch of straw laid on the bare ground as a bedstead; the only pair of boots owned by one of them was falling to pieces in tatters. Men I have seen were dressed in torn garments and their children were in rags. One of my colleagues had to live on wayside herbs for three days and three nights and his wife shared his fate! A professor of a university, bereft of everything, was, when I saw him, in dire want of a bed, and another of equal academic standard was wandering haggard over the countryside, searching in vain for a beloved family. And some of our ranks have been taken as hostages, others have been shot, and their widows and orphans have been left deprived of everything.

This description presents a genuine picture of the distress of the Belgian medical profession, but when these educated people are struck down by want they will never beg for charity: it must be brought to them. It is impossible to calculate how many of them are in this sore distress, and some have been so for days and weeks, but it is easy to see that the distress must be very widespread. Considering now the medical men only, Belgium contained 4800 doctors; the number of localities that have been destroyed is roughly as follows:—

Province of Brabant.—Londerzeel, Merchtem, Capelle-au-bois, Kotselaar, Wildouck, Cortenberg, Gelroode, Nieuwenrode, Wavre, Eppeghem, Beyghem, Ottignies, Mousty, Louvain, Jodoigne, Linsemaux.

Province of Limbourg.—Haelen, Lanacken, Tongres (partly).

Province of Liége.—Liége (partly), Mouland, Bermont, Visé, Micheroux, Batisse, Herve, Hermée, Milmont, Flemalle, Francarchamps, Lincent, Huy, Seilles.

Province of Namur.—Namur (partly), Bierwart, Narille, Tamines, Faliseulle, Andenne, Spontin, Evrehailles, Houx, Yvoir, Dinant, Bovinure, Anhage, Hartiere, Sommière, Walcourt, Mariembourg, Dourbes.

Province of Hainaut.—Charleroi (partly), Montignies, Morlanwelz, Gouy-les-Piéton, Lobbes, Beaumont, Frameries (partly), Merbes, Jemappes, Quaregnon, Marchienne.

Province of Luxembourg.—Rossignol, Etalle, Ethe, Florenville, Virtey, Arlon, Neufchateau, St. Hubert, Anthee, Arsimont, Marche, &c.

The deserted province of Antwerp and both the provinces of Flanders have been battlefields since one month, with the great struggle raging round Dixmude, Nieuport, Courtrai, Middelkerke, Ostende. What remains of those places to-day?

Each of those localities has its doctors and pharmacists, and at least 1000 of the doctors are now absolutely poverty-stricken, and 2000 to 3500 doctors are suffering cruelly through this war. We had 1800 pharmacists all over the country, and at least 300 of them are unable to earn their living, and all of them, with very few exceptions, are deprived of the most necessary trading stock. I dare say that my estimate is below reality.

Consider the immense suffering that our medical brethren have gone through and are still going through. Their pathetic and lamentable distress should unite all in the desire to relieve it. These practitioners have given a lesson to the world of unfaltering energy, but now their breaking courage will have to be kept up. In this emergency I call on the medical profession of England to rally to our help. It will be for us a great debt of honour and of eternal gratitude.

THE WAR.

THE CASUALTY LIST.

THE following casualties among officers in the Royal Army Medical Corps and Indian Medical Service serving with the Expeditionary Force have been reported since our last issue:—

Killed: Captain Ernest Mure Glanvill, R.A.M.C.; Captain Angus McNab, R.A.M.C. (T.).

Died of Wounds: Captain Thomas McCann Phillips, R.A.M.C.; Captain Charles Paget O'Brien-Butler, R.A.M.C.; and Lieutenant M. Richardson, R.A.M.C.

Wounded: Major F. S. Irvine, R.A.M.C.; Captain H. S. Dickson, R.A.M.C.; Captain A. E. Grisewood, I.M.S.; Captain W. F. M. Loughnan, R.A.M.C.; Captain K. Comyn, R.A.M.C.; and Lieutenant L. R. Shore, R.A.M.C.

Wounded and Missing: Captain A. M. Rose, R.A.M.C.

Missing: Lieutenant J. G. Butt, R.A.M.C.; Lieutenant N. M. Mehta, I.M.S.; and Lieutenant H. G. Winter, R.A.M.C.

Captain C. W. Holden, R.A.M.C., and Captain A. A. Meaden, R.A.M.C., previously reported wounded and missing; Captain R. V. Dolbey, R.A.M.C., and Captain R. A. Flood, R.A.M.C., previously reported missing; and Captain W. P. Croker, R.A.M.C., are now unofficially reported prisoners of war.

CAPTAIN H. S. RANKEN, V.C.

In the first list of nine officers and non-commissioned officers to whom the Victoria Cross has been granted for conspicuous bravery while serving with the Expeditionary Force appears the name of Captain Harry Sherwood Ranken, R.A.M.C., who died at Braisne on Sept. 25th from wounds received in action. Captain Ranken, whose obituary notice appeared in our issue of Oct. 24th, was awarded the Victoria Cross "for tending wounded in the trenches under rifle and shrapnel fire at Hautvesnes on Sept. 19th, and on Sept. 20th continuing to attend to wounded after his thigh and leg had been shattered."

THE SURGERY OF THE WAR FROM THE FRENCH STANDPOINT.

We have published many articles from the pens of British surgeons on their experiences of the war. The views of an eminent French surgeon will therefore be of all the more interest. At the Académie de Médecine of Paris M. Tuffier, who had been sent by the Minister of War to inspect the arrangements for the treatment of the wounded of our gallant Allies from the fighting line in the Vosges to the base hospitals, has given his conclusions. He considers the superiority of antiseptic over aseptic treatment incontestable and the drainage of infected wounds a procedure which nothing equals. The conservation of wounded limbs, a practice defended by the French school against amputation recommended by the Germans, is adopted in all the hospitals, but discrimination is necessary because of the dangers of emphysematous gangrene and septicæmia. M. Tuffier finds that in general the gravity of wounds increases progressively according as they are due to rifle bullets, shrapnel, or shell fragments. The gravity of the wounds produced by the last and the dangers of gangrenous septicæmia and tetanus make him regard immediate extraction of the fragment as indicated when this can be easily done. Compound fractures of limbs, other things being equal, are graver the nearer they are to the trunk, especially in the femur. Bullet wounds of the chest which come under treatment in hospitals have proved remarkably benign; cases of hæmothorax necessitating operation are exceptional. M. Tuffier was shown cases of large apertures of exit of projectiles as evidence of the use of explosive bullets. This charge is constantly being made by all the armies engaged in the war and has been discussed in our columns. It has been levelled against the Allies by the German press. M. Tuffier gives the explanation of many injuries attributed to the use of explosive bullets. The terrible wounds are due, he says, to the bursting on a bone of the hard envelope of an ordinary bullet or to the carrying away of a piece of bone—an explanation with which all experts are agreed. The use of a bullet prohibited by the rules of warfare can be proved only by the finding of such in the possession of a soldier. On the field of battle French "first aid" consists in the "parsimonious" application of tincture of iodine to the wound, an aseptic compress, a little cotton-wool, and a bandage. These are often alone sufficient in the case of simple wounds to ensure healing. In the field hospitals are retained the cases too serious to be sent to the base hospitals—wounds of the abdomen and chest, fractures of the upper third of the femur, and cases of hæmorrhage. M. Tuffier insists that in these hospitals there should be skilful surgeons capable of rapidly seizing the opportunity of performing any operations which may be necessary and which the organisation and equipment permit. But he does not think that laparotomy and suture of the intestine for abdominal wounds can be performed with any chances of success in a place where operations are being performed on septic cases, and where time is wanting. However, if percussion shows a large intra-abdominal effusion—a frequent condition—suprapubic incision under local anæsthesia and drainage may be performed. The usual treatment of abdominal wounds is to place the patient in the sitting posture, for him to abstain from all food, and to maintain these conditions until arrival at a completely equipped hospital. The treatment of tetanus—a frequent complication from contamination of wounds by the soil—should, M. Tuffier says, be preventive. The surgeon should endeavour to destroy on the first dressing any germs which may have gained access to the wound and should inject antitetanic serum as soon as possible. The urgency of the latter measure is shown by the case of an officer wounded in the battle of the Aisne by a fragment of shell which tore away all the metacarpal bones. Although he was injected on the second day after the injury, symptoms of tetanus appeared five days later and he succumbed. The most frequent grave complications are infections of fractures and wounds of joints, particularly of fractures of the upper third of the femur. In such injuries removal of projectiles and pieces of garment carried in by them and of free bone splinters and drainage should be carried out. The most serious complication is emphysematous gangrene, which should be treated at its onset by the actual cautery and injections of hydrogen peroxide.

MEDICAL PREPARATIONS FOR WAR IN THE OVERSEAS DOMINIONS.

At such a time as this the medical man is peculiarly fortunate. Little or no military training is necessary for his conversion into a serviceable member of His Majesty's army. It is therefore not surprising to find that the medical men of Britain beyond the seas are displaying in their own particular way that enthusiasm to serve which is one of the most remarkable features of this world-wide crisis. The Canadian medical journals are full of evidence of this spirit. Name after name is given of medical men who have volunteered for service. Not the least remarkable of these is that of Dr. J. G. Adami, professor of pathology in the McGill University, who has volunteered for service as a private. From the *South African Medical Record* of Oct. 10th we learn that the practitioners of the Orange Free State and Basutoland have made arrangements for working the practices of those called up by the mobilisation orders, so that they may suffer a minimum of loss. This journal comments favourably upon this step, and advocates its adoption throughout the Union. In a leading article entitled "Volunteer!" the *Medical Journal of Australia* details the steps already taken to provide the next Australian Expeditionary Force with a medical service. Behind the regimental medical officers with stretcher-bearers in the firing line there are light horse field ambulance wagons—an Australian device. Behind these, again, are the field and base hospitals. The personnel needed to man this organisation must include 92 medical officers. To this number must be added 60 medical men who have already volunteered for service with the first Expeditionary Force, and approximately 100 needed for the navy and for the Army Medical Reserve Corps on duty in Australia. The total number of medical men will therefore be about 250, actually about 10 per cent. of the whole Australian profession. This is a very remarkable figure, and one of which our Australian colleagues may indeed be proud. But the editor of the journal is not quite satisfied with it. He urges upon all those who are not serving their Empire in this direct manner the need for caring for those patients at home whose medical men have gone to war.

A VISIT TO CALAIS AND DUNKIRK.[1]

Our Special Sanitary Commissioner, who has been detailed for official work overseas, sends us the following account of a visit to Calais and Dunkirk:—

Calais, Nov. 11th.

No continental landing stage is better known throughout the world than the Gare Maritime at Calais. Whether the traveller from England is bound to Paris or Petrograd, the Italian lakes or the Black Sea, Egypt or India, he will in all probability land at Calais. But what a changed Calais it is in which I find myself to-day. There is no Dover boat, and no travellers for business or pleasure; there are no tourists. There is but one solitary passenger boat, which arrives late in the evening, and comes from Folkestone, not from Dover, and the vast majority of those on board are not passengers in the usual sense of the term. They are Belgian soldiers who have recovered from their wounds, or Belgian conscripts or volunteers, one and all going to join their regiments. The few English or other passengers, the rare travellers who have actually paid for their fare, are connected with the Red Cross, or, in any case, are going over for some grim war purpose. The polite stewards and helpful sailors, always anxious to render some small service in anticipation of a disproportionately large gratuity, have disappeared, as also the smartness and tidiness of the ship. Soldiers are lying on the decks, playing cards, smoking everywhere. The scene is more like a rough bivouac than a luxurious Channel passenger steamer. Nor did we get aboard the ship in the old easy way. In the train from London a yellow card has to be filled up stating where the traveller is going and why he is going there. On leaving the train at Folkestone he presents this card, which is kept by the authorities, while he shows his passport. This document, with proper *visé*, has to be shown again, and perhaps several times, before he can go on board, and, of course, before he is allowed to land at Calais.

---

[1] This article has been submitted to the Press Bureau, which does not object to its publication, as censored, and takes no responsibility for its correctness.

Military Occupation of the Calais Landing Stage.

Only dim lights are to be seen on the once brilliantly illuminated Calais landing stage. On entering the station building, instead of ticket collectors, we found Red Cross nurses, wearing their aprons, a white cloth to cover their hair, and in every other way ready to dress wounds and give help to the sick or wounded. And any number of Belgian soldiers crowded the station. The French Custom House officials had nearly all gone to the front; no one took the trouble to inquire about or look into my handbag. On the other side of the station the lines looked blank and deserted. There was not a train to be seen anywhere, and there was neither a carriage nor even a hand truck in which to wheel luggage along. Such commodities were, I was assured, superfluous, as there was not a bed to be had in the town, so it was no use going to inquire about one. To judge by the condition of the hotel adjoining the Maritime Station the report seemed true, while the station was full to overflowing, and every box, case, hamper, or bale of goods was being used as a seat, and every corner where it was possible to squat on the ground was already occupied by weary Belgian soldiers. The position was awkward, as I was accompanying a lady doctor and nurse, and felt responsible for their well-being. Fortunately a Belgian officer remembered having met me at an international congress, and as soon as I had someone in authority to intercede in our favour I felt reassured. In the end we were allowed to grope our way through the darkness back on board the ship we had travelled in. There were no beds but small state cabins where we slept on hard couches.

Calais as an "Evacuated" Town.

The next morning an eminent Belgian surgeon came to our rescue and conveyed us to the town in his ambulance motor. The doctor was under orders to proceed to another part of France, the nurse was then and there taken to a new hospital in course of formation, and I found an hotel where they allowed me to occupy for one night the room of an officer who was at the front. As for the following night, that would depend if some other room became vacant and if I succeeded in obtaining permission to remain in Calais, for I was in this unenviable position that I could not stop more than 24 hours without a permit, nor could I leave the town without a permit. My passport was no use in itself, but only of use in getting the necessary documents.

Calais, like Dunkirk, is legally speaking an "evacuated town," yet it contains such a crowd that it is almost impossible to find a bed, and at the hotels people are sleeping on sofas, on the floor, or on billiard tables. The fact is that while the presence of ordinary travellers is not allowed there are any amount of soldiers and of Belgian refugees. Indeed, the majority of the population of Calais consists of Belgian soldiers and Belgian fugitives. The famous city has been made over to the Belgians as Boulogne has been selected for the English. Belgian gendarmes, fully armed, pace the streets in couples, instead of the ordinary French police. If asked the way, they reply they are strangers and have no knowledge of the town. If after trying the public authority in vain I applied to an ordinary civilian the result was likely to be the same. He also generally proved to be a stranger, a Belgian just escaped from the devastation of his own country. Under these circumstances I did not find my way easily to the hospitals and the medical men whom I wanted to see.

Great delay, combined with a considerable amount of physical discomfort, is caused by the obligation to obtain from the Military Governor of Calais a special written permission for nearly every action, but considering the critical military circumstances of the campaign and the knowledge that Calais is the direct object of furious attack, we can wonder at no precautions—all are justified. That the permit to remain in or to go out of the town must be secured on each occasion is reasonable. Every telegram must be written in French and bear the stamp of the military governor before the post will accept it. This means constant visits to headquarters, where there is no waiting-room. Here I permit myself a grumble. The precautions I accept as necessary, but I think that the convenience of the public might be studied a little more. A large and mixed crowd stands in the street till the authorities have sanctioned or refused the request made in writing and which sentinels carry in. It may be necessary to wait for more than an hour, without a seat, exposed to all weathers. Among the crowd there are many women, some with children in their arms and some with infants at their breasts. I could not but think that such exposure if unnecessary was cruel and dangerous. An awning, at least, might be provided or a large tent put up in the yard beyond the entrance, with seats and a stove inside. The perpetual excuse made that "this is war," or in French, "*à la guerre comme à la guerre*," is all very well at a moment of emergency, but several weeks is more than a moment, and there has been plenty of time to show some consideration for the hundreds of people who are daily compelled to stand and wait in the street.

The Transport of the Wounded to England.

As far as possible all the English wounded are sent to Boulogne, though some British wounded have strayed into Calais. The plan is, however, that all the Belgian wounded shall be sent to Calais and thence to England if well enough to travel. At first there is no doubt that some wounded were put on board who were not fit to travel, especially by sea, and a few did not survive the fatigue of the journey. Consequently efforts were made to increase the hospital accommodation at Calais so as to retain a larger number before exposing them to the risk and fatigue of crossing the Channel, with the chance of adding sea-sickness to all their other sufferings. It is most unfortunate that the new station, now in the course of building on the Admiralty Pier at Dover, is not terminated. But the organisation by which the transport is made works perfectly.

The Enemy at the Door.

Of course, if the Germans captured Dunkirk, Calais, and Boulogne the whole situation with regard to the wounded would be altered at once, and those who not long ago were so fiercely critical of the treatment of the wounded did not recognise what military exigencies demanded. I was struck with the calm confidence of everyone at Calais when the enemy was indeed at the gate. When the Prussian Guards made their notable effort to reach us by attempting to break through the line of defence at Ypres no one appeared nervous. At Dunkirk, which was much nearer and where I proceeded the day after this tremendous onslaught, there was a ghastly accumulation of wounded, but no fear. The aeroplanes dropped bombs and killed women and children in Dunkirk. The German troops had approached a little nearer the day that I was there, for they occupied a part of Dixmude, which is reached from Dunkirk in a motor in less than an hour; but at Dunkirk, as at Calais, the utmost confidence and calm prevailed. We were all far more anxious about the wounded than about the Germans. We felt, and felt keenly, that the best was not being done for the wounded; but our faith in the Belgians, the British, the French, and the Indian soldiers, who were holding the trenches only a few miles away, was absolutely unbounded. Had they given way our lives would have been in the gravest peril. The German shells would have crashed into our hospitals as they have so often done before, and we could not possibly have removed all the wounded in time to save them from an enemy that was barely 20 miles away.

Hospital Requirements at Calais.

To return to the situation at Calais, there are things that need to be said, in my opinion and in the opinion of those whom I consulted on the spot. It is necessary to understand that the hospital base for the Belgian army is in England, and that Calais is only the port of embarkation. Therefore, the wounded are only retained in Calais when the injury they have received is so great that it would be dangerous to send them over to England. Consequently and happily there are not many wounded in Calais, so that there is not a pressing demand for either surgeons or nurses. Indeed, there are many army surgeons in Calais who have little or nothing to do. Highly skilled nurses are more needed, but what is specially required are one or two exceptionally distinguished and experienced surgeons. Surely there need be no trouble about this, if I am right; and whether I am right or wrong could be found out by the briefest inquiry. And if the services of a few additional surgeons of high experience are wanted the need can be met without giving offence to anyone if the right steps are taken. There are desperate surgical cases at Calais that can only be saved by the exercise of high technical skill, and the presence here of one or two consultants not attached to any one particular hospital, but whose help could be secured for the worst cases in all the hospitals, without giving offence to the regular staff of those hospitals, would be of the highest value. It will be easily understood that as most of the cases are shipped off to England, what remains differs altogether from the average practice of field and base hospitals. The susceptibilities of three nationalities have to be considered, I am aware, but I have too good an opinion of them and of our own officials to imagine that questions of pique would arise. It is true that to avoid this Calais has been allotted to the Belgians as Boulogne to the British. Nevertheless, the Union des Dames de France has a French hospital, and the British Red Cross Society has an English hospital both in different parts of the same building in Calais. Also, though there is a vast predominance of Belgian wounded at Calais, it has been impossible to exclude altogether French and British wounded. In the same way the surgeons and the nurses belong to the three nationalities, with a small sprinkling of volunteers from Russia and other countries. It needs some diplomacy to make all these heterogeneous elements work together.

OBITUARY OF THE WAR.

ANGUS MACNAB, M.B., CH.B. EDIN., F.R.C.S. ENG.,

CAPTAIN, LONDON SCOTTISH REGIMENT.

Captain Angus MacNab, who was ophthalmic surgeon to King Edward VII. Hospital, Windsor was killed in the first engagement of the London Scottish Regiment whilst serving in a medical capacity. He was a brother of the Hon. Robert MacNab, formerly Minister of Agriculture in New Zealand. He graduated in arts at Otago, New Zealand, and in medicine at Edinburgh University. Subsequently he devoted himself to ophthalmology and studied at the Moorfields Eye Hospital, where he became a chief clinical assistant, and at Freiburg and Vienna. At the time of his death he was clinical assistant in the ophthalmic department of Charing Cross Hospital. MacNab was a man of great energy and acumen. His facility in learning the German language much impressed Professor Axenfeld when he was working in Freiburg. He translated Axenfeld's "Bacteriology of the Eye"—the standard work on this subject—and Lohmann's "Disturbances of the Visual Functions." He, who so fully proved his appreciation of the benefits of German science, fell a victim to *Kultur* in its most repellent form. A report by a motor-cyclist despatch rider says he "was actually bayoneted in front of their eyes whilst bending down attending to two wounded men. It was bright moonlight, and he had a white badge and Red Cross on his arm and even a blue tunic on, so as to be absolutely unmistakable, and was of course without arms of any sort." It is by such dastardly deeds that we learn that *Kultur*, which once stood for civilisation, now means ultra-barbarism.

CHARLES PAGET O'BRIEN-BUTLER, L.R.C.P. & S. IREL.

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain Paget O'Brien-Butler, who has died of wounds received in action, was the son of the late Major Butler, formerly a racing official in Ireland. O'Brien-Butler received his professional education in Dublin, and took the Licences of the Royal Colleges in 1905. He soon entered the Royal Army Medical Corps. Both before and after qualification O'Brien-Butler was one of the best known amateur riders in Ireland. In 1907 he topped the amateur riders' list. At some meetings he rode every winner of the day. On going to India he became equally famous as a rider. As lately as August 5th in the present year he rode a race at Galway, leaving immediately afterwards for active service. O'Brien-Butler was very popular as a rider; he was plucky and clever, and was recognised as a thoroughgoing sportsman.

THOMAS MCCANN PHILLIPS, M.B. R.U.I.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

News has been received in Belfast of the death of Captain T. McCann Phillips in No. 4 Clearing Hospital, Flanders, from wounds received in action. A son of the Rev. J. G. Phillips, of Damascus, who married a Belfast lady, the late Captain Phillips received his early education in Trent College, Nottingham, and in Campbell College, Belfast. He studied at Queen's College, Belfast, and in 1905 graduated M.B. of the Royal University of Ireland. He was a house surgeon at the Royal Victoria Hospital, Belfast, and shortly afterwards entered the Army Medical Department, gaining first place at the examination. He was home on leave from India when the war broke out, and was posted to Victoria Barracks, Belfast. Although only sent to the front on Oct. 3rd he had seen some desperate fighting, especially round Ypres, being continuously in the firing line during his tragically short service. Captain Phillips was most popular, a good athlete, a man of decided ability, and very kindly and sympathetic. He was unmarried, and great sympathy is felt for his mother, who is a widow, and for his brother, Dr. Walter Phillips, who is a lecturer in the Union Medical College, Moukden.

JAMES HENRY DIGBY WATSON, M.B., CH.B. EDIN.,

TEMPORARY SURGEON, ROYAL NAVY.

J. H. Digby Watson, who lost his life while serving as temporary surgeon in H.M.S. *Hawke* when she was torpedoed on Oct. 15th, was born on August 31st, 1890. He was the son of Engineer-Captain Watson, R.N., and was educated at King's School, Canterbury, Edinburgh Academy, and the University of Edinburgh. At school and college he soon made a name for himself as an all-round athlete, and last winter when he was working at the London Hospital he gained his Rugby International cap for England, playing with great success as a three-quarter against Scotland at Inverleith. He was also a good cricketer, boxer, and high jumper; while in 1912 he won the long jump in the Scottish inter-university sports and in the international athletic contest between Scotland and Ireland. He obtained his medical qualifications at the close of last year, graduating M.B., Ch.B. in the University of Edinburgh on Dec. 17th, and joined the *Hawke* at the beginning of August. His cheerful disposition and independent character, as well as his athletic prowess, endeared him to many friends, and his death at the early age of 24, while in his country's service, is one of the many tragedies of the present war.

The British Red Cross Society.—The summary of the work for the week ending Nov. 17th states that the number of hospitals accepted by the War Office to date is 417, containing beds for 12,749, including 1019 beds accepted during the past week, and distributed among the Army Commands as follows: London, 795; Southern, 3865; Aldershot, 687; Eastern, 3507; Northern, 2034; Western, 1654; Irish, 207. A number of Red Cross Voluntary Aid Detachments are being utilised in connexion with these hospitals. The Weir Hospital, Balham, which has been taken over by the Kensington Division of the British Red Cross Society, has been inspected and approved. Viscountess Ridley's house in Carlton House-terrace, and Evelyn Lady Alington's house, 41, Portland-place, have been inspected with a view to their being converted into hospitals for officers.

At the Netley Red Cross Hospital 300 beds are now available. Three orderlies' huts are nearly completed, and the large dining hall for patients will be ready on Nov. 25th. Her Majesty Queen Alexandra has been graciously pleased to present 400 yards of lawn muslin for puggerees for the wounded Indian soldiers. Messrs. Liberty and Company have also given 420 yards of material for puggerees. There are to-day 153 British and 60 Indian patients in the hospital.

Motor ambulances have been coming in. From noon on Tuesday, the 10th inst., until to-day 50 ambulances and cars and two lorries have been despatched. A falling off has occurred in despatch during the last two or three days of this week owing to the congestion of cars at Folkestone. These could not be shipped over owing to the heavy seas.

Nurses have been posted for duty in Home Military Auxiliary Red Cross Hospitals as follows: Nov. 11th, Sturminster Marshall, 1; Milton Hill Hospital, Abingdon, 1; Nov. 12th, Waverly Abbey, Farnham, 1; Exeter, 1; Nov. 13th, Stourbridge Red Cross Hospital, 3; Nov. 14th, Clandon Park, 1; Beckett Hospital, Barnsley, 2; Louth Hospital, Lincolnshire, 2; Hon. Mrs. R. Lindsey's Officers' Hospital, 2; Southampton Docks Red Cross Hospital, 1; Nov. 16th, Countess of Normanton's, Ringwood, 1; Bighton Wood, Alresford, 1; Frinton-on-Sea Red Cross Hospital, 2; St. John's Hospital, Abbeydale, Sheffield, 1; Nov. 17th, Countess of Normanton's, Ringwood, 1; Brentwood, Essex, 1; making a total of 22.

The following stores have been despatched during the past week: 1002 cases of goods to France, and 271 have been distributed in England, while 90 home hospitals have also been supplied. Medical stores to the value of £3500 have been purchased. The increase on this account has arisen owing to the special consignment sent to the British Red Cross Hospital at Netley. 28,465 garments and pieces of linen have been received, while 39,139 articles have been despatched. The number of gifts of garments and linen shows a great falling off, and it is hoped that a more ready response will be forthcoming with these requisites.

A large number of personal inquiries continue to be received with regard to prisoners of war, but the society has only been able to satisfy a small proportion of these. Daily communication is maintained with Geneva and with Sir Walter Lawrence at the Prisoners of War Bureau.

The society has issued full rolls of Voluntary Aid Detachments mobilised up to Nov. 17th, of British Red Cross detachments employed but not mobilised, and of personnel posted for duty abroad.

The British Medical Association and the Belgian Medical Refugees.—Many communications have been received at the central office of the British Medical Association from members of the medical profession who are anxious to provide hospitality for Belgian medical men and their families at present in this country. The Medical Secretary has offered to the War Refugees Committee at Aldwych the use of the office of the Association as a clearing house, collecting through the *British Medical Journal* the names of medical men wishing to offer hospitality, inquiring as to the nature and extent of the offers made, and transmitting the particulars to the War Refugees Committee. Lord Gladstone has welcomed the coöperation of the Association. Medical men, or the wives of medical men, who are willing to offer hospitality to Belgian medical men and their families are invited to write to the Medical Secretary of the Association stating what hospitality they are prepared to give, and any such offers will be dealt with as promptly as possible. The refugees themselves greatly prefer to be dealt with as families and not as individuals, and this has been adopted as the general policy of the War Refugees Committee.

Military Medical Arrangements in Austria-Hungary.—The American medical profession is not content to stand aside with folded hands watching the wholesale slaughter that is engrossing Europe. It is true that one or two of the medical journals, like some of the lay periodicals of America, are adopting a rather supercilious attitude of virtuous surprise at the madness that has possessed the Old World; presumably these journalists are too young to know anything of the internal struggle that convulsed the United States only 50 years ago. These are, however, in a minority. The general attitude of the American, whether doctor or layman, is one of anxiety to alleviate suffering. Among their many efforts in this direction—efforts which the armies on both sides most gratefully acknowledge—is to be included the despatch of two Red Cross units to Austria-Hungary. These reached Vienna *viâ* Rotterdam on Oct. 14th, one being retained there while the other went on to Budapest. Count Rudolf Traun, who welcomed them on behalf of the Austrian Red Cross Society, said that America was the only neutral country sending medical and surgical help to the European combatants. "A report received from Budapest on Oct. 21st," says the *Boston Medical and Surgical Journal* of Oct. 29th, "states that the American Red Cross unit assigned to that city has been put in charge of a hospital of 180 beds in the Wechselmann Institute for the Blind." It appears, further, from their report that the capital of Hungary is flooded with wounded soldiers who continue to arrive daily in trainloads. (It should be recollected that the battle front in Galicia is about 300 miles distant from Budapest, while the Austro-Serbian line of contact is about 200 miles away.) A new military hospital just opened has 3600 beds, and another barrack hospital has been started which will accommodate 4000 sick or wounded. To meet the immense demand for medical men created by this influx of wounded the Ministry of Education has agreed that students in their fourth and fifth years entering the military hospitals may count the time as a portion of their hospital year. At Trieste and other towns in Southern Austria large numbers of wounded are being received. Convalescent soldiers sent home on furlough are said to be without means of subsistence, so that, in addition to their ordinary pay, the War Office has found it necessary to give a daily sum of 70 kreuzers (about 1*s.* 3*d.*). Italian newspapers state that cholera is rife in Galicia and Hungary, but this happily is unconfirmed as yet.

Accommodation for Wounded Soldiers in Dublin.—The last party of wounded which arrived in Dublin has exhausted the accommodation available in the Dublin hospitals. Moreover, the nature of the wounds is such that the pressure is not likely to be relaxed for some time. Acting on the advice of Surgeon-General Anderson, the City of Dublin Branch of the British Red Cross Society has decided to make the provision of further accommodation for wounded soldiers its first task. It is believed that at least 500 beds will be required in the near future. Several alternative schemes have been under discussion by the committee. It was suggested to erect temporary buildings in some open space such as Phœnix Park; on the other hand, it was suggested to obtain some public building for use as a hospital, or to make the necessary changes in a row of houses; finally, it was suggested that temporary buildings should be erected in connexion with the existing general hospitals. Many of these institutions are possessed of vacant spaces of land adjoining their present buildings, and it should be possible to find space for 500 beds in this way without difficulty. The last-mentioned proposal received most support. It was felt that it solved at once all the questions of management and staff which would arise if a new hospital were erected. A small committee was appointed to get into touch with the hospitals and find what space they had available, and whether they would coöperate in the carrying out of such a scheme.

CARE OF THE WOUNDED IN SCOTLAND.—The arrangements for the distribution in Scotland of the wounded to auxiliary hospitals and convalescent homes, which was under control of the central registry under Major Tudor Craig, have now been discontinued, and the work has been entrusted to the Scottish branch of the British Red Cross Society. The military authorities have also announced that wounded will only be sent to auxiliary hospitals and convalescent homes which have obtained the sanction of the society through its executive, and have been approved on examination by the military authorities. The distribution of cases will be in the hands of the commissioners for the respective districts, and they will decide which institutions are to be ranked as auxiliary hospitals where the grant of 2*s*. per head per day will be given by the military authorities.

Lieutenant-Colonel J. Oldfield, R.A.M.C. (T.), commanding 3rd Reserve East Anglian Field Ambulance, writes from the Drill Hall, Walthamstow, to say that he will be pleased to hear from any medical man who wishes to obtain a commission.

There will be vacancies shortly in Field Ambulances earmarked for foreign service as well as in the Reserve Field Ambulance for home service. There will also be vacancies in combatant units for regimental medical officers. For a man who wishes to go abroad or who wishes to become a regimental medical officer it is always advisable that he should as soon as possible become attached to a field ambulance for training.

WAR GIFT FROM THE MEDICAL MEN OF ESSEX.—The members of the medical profession in the county of Essex have subscribed a sum of over £420, and have purchased therewith a fully equipped motor ambulance with four stretchers, &c., and have presented it to the War Office for use of the wounded in France and Belgium. The subscriptions have been obtained by the various medical officers of health in the county, and a complete list of the donors can be seen at the office of the county medical officer of health in Chelmsford. The ambulance will bear a brass plate, on which will be inscribed: "This Ambulance was Presented to the War Office by the Members of the Medical Profession in Essex, England, November, 1914."

INDIAN GIFTS FOR THE SICK AND WOUNDED.—It is announced that owing to the very generous response of the public from all parts of India a sufficient number of the original ten-bed units of Red Cross gifts for the sick and wounded of the Indian Expeditionary Force has already been received. This does not mean that no more gifts will be needed, but that in future the provision of comforts will be materially modified, and the St. John Ambulance Association is therefore issuing a revised list of all articles it is considered desirable to renew, repeat, or replace. A large supply will be required to replace articles expended at the front. Naturally more gifts will be required for Indian than for British troops, and it is suggested that the proportion of Indian to British should be three to one.

CHOLERA IN AUSTRIA.—According to Austrian official reports published on Nov. 5th and referring to the week from Oct. 21st to Oct. 28th, 645 new cases of cholera were notified in the Austrian empire. These notifications referred to 60 or 70 localities. The following places seemed to form centres for the spread of an epidemic: Vienna, 14; Trappau, 20; Bereska, 23; Taliska, 24; Balygrod, 47; Krems, 105; Rozborg, 82. All the cases notified had occurred among soldiers returning from the battlefields.

A COMMITTEE has been formed in New York, under the auspices of *American Medicine*, for the collection of a fund for the relief of doctors in Belgium. The committee includes the names of Dr. W. S. Bainbridge, Dr. S. Ely Jelliffe, Dr. W. H. Porter, Dr. Parker Syms (of New York), and Dr. Charles E. de M. Sajous (of Philadelphia). It will work in coöperation with the Belgian Relief Committee.

APPLES FOR THE FRONT AS AN ANTISCORBUTIC.—Dr. H. Benjafield, of Moonah, Tasmania, in a letter dated Sept. 10th, calls attention to the importance of supplying our soldiers at the front with fresh fruit, especially apples, as a preventive against scurvy. He quotes the testimony of Dr. Buzzard, in "Reynolds's System of Medicine," based on his experience in the Crimean war of 1854, when the allied army had 25.000 men suffering therefrom, of whom thousands died, while the suffering from wounds and other diseases is increased thereby He suggests that Australia should begin at once to organise for the despatch of apples against the winter. At least 50,000 cases a week will be required. Doubtless when the need is realised much will be given, but measures should be taken also to purchase as near to cost price as possible. England should send her share, but he suggests that perhaps Canada and the United States would help. Dr. Benjafield points out that Professor McAlpine and others have shown that the health-giving properties of the apple are found in and immediately beneath the skin; consequently, a pound of sound two inch apples would contain more than a similar quantity of large fruit. The suggestion seems worthy of attention.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians on Oct. 29th and of the Council of the Royal College of Surgeons on Nov. 12th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the following 67 candidates who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the necessary by-laws:—

Ahmed Abdel-Al, Guy's Hospital; Bertram Pulvermacher Allinson University College Hospital; Lalit Mohan Banerji, L.M.S. Calcutta Calcutta University and St. Bartholomew's Hospital; George Arthur Batchelor, St. Mary's Hospital; William Arthur Hazlerigg Noel Bell, St. Thomas's Hospital; William Francis Bensted-Smith, Cambridge University and Middlesex Hospital; Geoffrey Alwyn Gershom Bonser, B.A. Cantab., Cambridge University and St. Thomas's Hospital; William Edward Hugh Bull, B.A. Cantab., Cambridge University and London Hospital; Percy Herbert Burton, London Hospital; Sam Nathaniel Cohen, Leeds University; Gordon Cranstoun, B.A. Oxon., Oxford University and St. Thomas's Hospital; Harold Armstrong Crouch, B.A. Cantab., Cambridge University and London Hospital; John Duncan Legge Currie, Cambridge University and St. Bartholomew's Hospital; Delphine Gertrude D'Abreu, L.M.S. Punjab, Lahore University; John Edgar Davies, Guy's Hospital; John Llewellyn Davies, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; John Rhys Davies, Cardiff and Middlesex Hospital; Frederick Henry Dodd, Guy's Hospital; Hugh Alderson Fawcett, University College Hospital; Herbert Leslie Garson, B.A. Cantab., Cambridge University and St. Thomas's Hospital; James Alfred Gregory, Manchester University; David William Griffith, Cardiff and St. Thomas's Hospital; Stanley Sextus Barrymore Harrison, Guy's Hospital; William Clavering Hartgill, Otago University and London Hospital; Mary Isabel Hemingway, Birmingham University; Alec George Holman, London Hospital; John Christopher Jones, M.B., Ch.B. Birmingham, Birmingham University; Tom Ramsden Kenworthy, St. Bartholomew's Hospital and Leeds University; Geoffrey William King, Guy's Hospital; Louis Gaston Le Blanc, St. Bartholomew's Hospital; Helena Rosa Lowenfeld, Royal Free Hospital; Henry Wingate Maltby, St. Bartholomew's Hospital; Pestanji Manekji Masina, L.M.S.S.A. Lond., Bombay University and University College Hospital; Gerald Woffindin Maw, University College Hospital; Percy Uvedale Mawer, St. Bartholomew's Hospital; James Allen Montgomery, M.D. Manitoba, Manitoba University and London Hospital; William Howard Nicholls, Guy's Hospital; Arthur Henry Pemberton, University College Hospital; Alan Cecil Perry, London Hospital; Baddelianage Don Hugo Philip, L.M.S. Ceylon, Ceylon Medical College and London Hospital; H. Rivers Pollock, B.A. Cantab., Cambridge University and King's College Hospital; John Sandys Pooley, Cambridge University and St. Thomas's Hospital; Reginald Norman Porritt, B.A. Cantab., Cambridge University and London Hospital; Frank Greenhalgh Prestwich, Manchester University; Nicholas Purcell, M.B., Ch.B. Edinburgh, Edinburgh University and London Hospital; Philip Hugh Rawson, London Hospital; Geoffrey Stanhope Robinson, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Clive Watney Roe, Charing Cross Hospital; William Albert Rogerson, Manchester University; William Hugh Cowie Romanis, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Pinthu Sai, Cambridge University and St. Thomas's Hospital; Mary Schofield, Royal Free Hospital; Donald Charles Scott, Durham University and Guy's Hospital; Edward Wheeler Scripture, M.D. Munich, Munich University and St. Bartholomew's Hospital; John Hunter Sewart, University College Hospital; Peter de Safforie Smith, Birmingham University; Harry Neville Stafford, B.A. Cantab., Cambridge University and St. Thomas's Hospital; John Frank Herbert Stallman, Guy's Hospital; Richard Patrick Aloysius Starkie, Cambridge University and St. Thomas's Hospital; Horatio Thomas, B.Sc. Lond., University College, Cardiff, and St. Mary's Hospital; John Oscar Thomas, King's College and Westminster Hospital; William Godfried Lorenz Wambeek, Ceylon Medical College and Middlesex Hospital; John Rollo Noel Warburton, St. Thomas's Hospital; Watkin Watkins, University College, Cardiff, and University College Hospital; Thomas Burges Welch, St. Bartholomew's Hospital; Douglas Henry David Wooderson, St. Bartholomew's Hospital; William Arthur Young, B.Sc. Lond., Guy's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Council conferred the Diploma of Fellow upon Robert Lister Horton, M.B., B.S. Lond., L.R.C.P., Lond., M.R.C.S. Eng., of University College Hospital, who has previously passed the examination and has now attained the requisite age of 25 years. The licence in Dental Surgery was also conferred upon Francis Arthur Everett, Charing Cross and Royal Dental Hospitals, who has passed the requisite examinations and has now complied with the by-laws.—At the Primary Examination for the Fellowship in Anatomy and Physiology, held on Nov. 4th, 5th, 10th, and 11th, 57 candidates presented themselves, of whom 15 were approved and 42 were rejected. Among the successful candidates were two ladies—Miss Bostock and Miss Ingleby, both of the London School of Medicine for Women. The following is a list of the successful candidates :—

Jugalkishor Adhya, M.B. Calcutta, Calcutta University and Middlesex Hospital ; Marion Noel Bostock, London School of Medicine for Women ; Leonard Snowden Debenham, Guy's Hospital ; Spencer Graeme Dunn, St. Bartholomew's Hospital ; Benjamin Thomas Edye, M.B., Ch.M. Sydney, Sydney University and University College ; Arthur Norman Hooper, B.A., B C. Cantab., M.R.C.S., L.R.C.P., Cambridge and Birmingham Universities ; John Basil Hume, St. Bartholomew's Hospital ; Helen Ingleby, London School of Medicine for Women ; Harold George Victor Mence, Birmingham University ; Arthur Eisdell Moore, M.D., Ch.B. Edin., Edinburgh University and St. Mary's Hospital ; Sydney Devenish Rhind, St. George's Hospital and King's College ; Tribhovandas Oghaddes Shah, M.R.C.S., L.R.C.P., Middlesex Hospital ; James Renfrew White, M.B., B.S. New Zealand, M.R.C.S., L.R.C.P., New Zealand University and Middlesex Hospital ; David Whyte, M.B., Ch.B. Otago, Otago University ; and Graham Selby Wilson, King's College.

THE next session of the General Medical Council will commence on Tuesday, Nov. 24th.

Mr. George Mitchell Winter, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., D.P.H., has been reappointed deputy mayor of Torquay for the sixth consecutive year.

UNIVERSITY OF CAMBRIDGE.—The Raymond Horton-Smith prize has been awarded to Philip H. Bahr, M.A., M.B. Cantab., for his thesis for the M.D. degree on the subject of Research in Sprue.

WE announce with much regret the death on Saturday last of Dr. Eustace Smith, the veteran authority on diseases of children, who was for 43 years a member of the active medical staff of the East London Hospital for Children.

MEDICAL CALLS TO THE BAR.—Dr. W. Collingridge, of Pembury, late medical officer of health, City and Port of London, was on Nov. 17th called to the Bar as a Member of the Honourable Society of Gray's Inn ; and on the same day Dr. James Campbell McNeillie, medical officer of the East Rand mines and hospital, was called to the Bar as a Member of the Middle Temple.

Dr. Aldo Castellani, Director of the Clinic for Tropical Diseases, Colombo, Ceylon, has been offered by the Italian Government, and has accepted, the professorship of tropical medicine in the University of Naples and the directorship of the Royal Clinique for Tropical Diseases in the same city. Dr. Castellani will take up his duties at the beginning of 1915.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 12th, with Sir Francis H. Champneys in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward. The midwife being guilty of misconduct in assisting an uncertified person to attend women in childbirth otherwise than under the direction of a qualified medical practitioner, and in aiding and abetting the aforesaid person to commit an offence against Section 1 (2) of the Midwives Act, 1902. The midwife not being scrupulously clean in her person, appliances, and house, as required by Rule E. 1 ; not taking and recording the pulse and temperature of the patient at each visit, as required by Rule E. 13. The advice of a registered medical practitioner having been sought, the midwife failed to notify the local supervising authority thereof, as required by Rule E. 21 (1) ; she washed the patient once only, and then did not comply with the antiseptic requirements of Rule E. 7. The patient suffering from loss of blood, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20 (2). That having been in contact with a person suffering from puerperal fever the midwife continued in attendance upon patients without having undergone any disinfection to the satisfaction of the local supervising authority, as required by Rule E. 5. Medical aid having been sought for a patient, the midwife neglected to send any notification thereof to the local supervising authority, as required by Rule E. 21 (1), and she neglected and declined to carry out the instructions of the doctor who had been sent for, as required by Rule E. 6. A child having died before the attendance of a registered medical practitioner, the midwife failed to notify the local supervising authority thereof, as required by Rule E. 21 (1), and she did not keep her register of cases as required by Rule E. 23.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Parliament and the War.

PARLIAMENT has assembled for a new session. It is understood that the sittings will not be prolonged and will be entirely devoted to dealing with the financial and other problems arising out of the war. New taxation is necessary, and also a war loan for £350,000,000. The Chancellor of the Exchequer has announced that the income tax is to be doubled. The full increase does not come into operation in respect of the current year, when the rates will be 1*s.* in the £ on earned income and 1*s.* 8*d.* on unearned. Next year the rates will be 1*s.* 6*d.* and 2*s.* 6*d.* respectively. The war has been costing this country from £900,000 to £1,000,000 a day, and Mr. LLOYD GEORGE estimates that for the first full year it will cost £450,000,000. No criticism has been made of the Government proposals, because in all quarters there is a profound feeling that the world should have the spectacle of a nation absolutely united in the great emergency with which we are now confronted.

HOUSE OF COMMONS.

MONDAY, NOV. 16TH.

British Medical Men in Germany.

Mr. HAY MORGAN asked the Secretary of State for Foreign Affairs whether any steps had been taken to secure the release of medical men who were British subjects detained in Germany; and, if so, whether he could give any indication as to the date when they would be allowed to return home.—Sir EDWARD GREY replied: His Majesty's Government were informed on Oct. 3rd that the German Government might allow doctors and ministers of religion to return from Germany, and on Oct. 8th His Majesty's Government made a definite offer of reciprocal treatment with regard to these and three other classes of persons. On Oct. 22nd His Majesty's Government were informed that the German Government had accepted the offer and would permit the departure of medical men and ministers of religion, and since then medical men have been returning, though a doctor was detained at Bad Nauheim until last week. The answer refers to civilians only.

The Health of the Troops.

Lord CLAUDE HAMILTON asked the Secretary of State for the Home Department whether His Majesty's Government would introduce and pass a measure empowering magistrates to issue warrants for the summary arrest of women of notorious bad character who were infesting the neighbourhood of the various military camps in the United Kingdom, to the detriment of the morals and health of the troops, and further to empower the magistracy to commit such women for detention in a hospital or reformatory until the close of the war.—Mr. MCKENNA said in reply: While the Government recognise the serious nature of the evil to which the noble lord alludes, I fear it would not be possible to deal with it effectively by such legislation as he recommends. We must rely partly on the organised efforts which are being made by voluntary women workers and partly on the firm enforcement of the existing law by the police and the magistrates.

Care of Soldiers' Feet.

Answering Sir CLEMENT KINLOCH-COOKE, Mr. TENNANT (Under Secretary of State for War) said: The arrangements for the employment of chiropodists in the regular army have been made applicable to the Territorial Forces.

Calf Lymph for the Army.

In reply to Sir CLEMENT KINLOCH-COOKE, Mr. TENNANT said: The vaccination lymph used in the army is obtained from the Local Government Board establishment at Hendon, and is believed to be the same as that supplied by the Board to public vaccinators.

The Wastage in the New Army.

In the course of the debate on the vote of credit Sir IVOR HERBERT remarked that there was an abnormal wastage going on in the ranks of units of the new army which had already been raised—a wastage which required some explanation and the adoption of measures to check it. According to figures which had been given to him, there had been a wastage in many units of as much as from 30 to 40 per cent. of the strength of the unit, and it was due to what was known in military language generally as "avoidable disease." It was a very serious question, and it was one which it behoved the Government and the military authorities to give close attention to, now that they were dealing with the question of raising a further number of recruits. It was unavoidable possibly that a large number of young men thrown into temptation which they had never faced before should suffer in the way which they had done. But at the same time it should have been evident to those accustomed to military organisation that special police measures were required to restrain the causes of this most unfortunate condition of affairs. At present, to put it plainly, the great wastage that was going on in the ranks of the new army came from two causes, and two causes only—drink and women. But both these were causes which could be dealt with by administrative measures, and he urged that some measures should be taken. If the powers in the hands of either the local bodies or the military authorities were not sufficient to restrain the sale of drink or the other social evil, then the Government should come to Parliament and propose such measures as might be necessary to enable them to deal with the problems. That anything like that wastage should be allowed to go on unchecked in the ranks of the new army was certainly a most serious matter. It had been a most distasteful and unpleasant thing for him to bring it before the House of Commons, and it was only a sense of duty and also the knowledge which he had gained of these things during his military experience that had induced him to rise and speak on this question.

Sir T. WHITTAKER urged the Government to take every means to check insobriety amongst recruits.

Mr. COURTHOPE doubted very much whether a single unit could be named in which either 30 per cent. or 40 per cent. of wastage had occurred. He would say without fear of contradiction that in the great majority of localities and the great majority of units the sobriety of the recruits had been very noticeable, and there had been an astonishing freedom from avoidable disease. In the unit with which he was connected, of some 1600 or 1700 men who had been up since the beginning of the war and stationed in places in which it might be expected that there would be temptation, there had not been a single case of venereal disease. He did not quote this as being exceptional, because he knew of scores and scores of units with an equally good record, but he did not want it to go out as the result of this debate that there had been a great prevalence of avoidable disease or excessive drunkenness.

Mr. ASQUITH (in his reply to the debate said): An honourable Member has raised the question of the alleged demoralisation through drink and other causes to which he adverted of a substantial proportion of the new army. I think that my honourable and gallant friend—I am sure quite unintentionally—took in this respect a much too gloomy view. We have made most careful inquiry into the matter, and to say that a percentage of from 30 to 40 of these men are disabled from preventable causes, from diseases, from serving their country in any useful manner is, I believe, entirely without any foundation. The Adjutant-General has made most careful inquiry into the matter. I do not commit myself to specific figures, but I believe that it would be far nearer the truth to say that there have not been more than 10, or at the outside 15, per cent. of cases of disease of every sort or kind, not only these particular ones, but all sorts of diseases of every kind, and on the whole I do not believe that there has ever been brought together a body of men who have comported themselves so well and shown such a regard for sobriety and decency of conduct as the new recruits for the army. Undoubtedly these men, as is always the case when a large aggregation of comparatively young men are brought together in this casual way, are exposed to temptation to which some of them are probably strangers and to which now and again individuals succumb. But I believe if you take the average standard of conduct that it is worthy of the country and worthy of the cause. But my honourable friend may be quite sure that the Adjutant-General, in conjunction with the civil authorities, is taking every possible step to remove all temptation and to secure the highest possible standard of sobriety and conduct in those troops.

WEDNESDAY, NOV. 18TH.

Medical Practitioners with Temporary Commissions.

Sir PHILIP MAGNUS asked the Financial Secretary to the War Office whether a medical practitioner now serving in the Royal Army Medical Corps with a temporary commission was entitled to a pension for wounds at the same rate and under the same conditions as officers holding permanent commissions; and whether, in the event of his death, his widow and orphans would be entitled to a pension, and, if so, at what rate.—Mr. H. BAKER replied: Yes, Sir; the rates and conditions are fully set out in the pay warrant.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CASTELLANI, ALDO, M.D. Florence, has been appointed Professor of Tropical Medicine in the University of Naples.

FERGUSON, J. J. HARROWER, M.B., Ch.B. Edin., has been appointed Medical Superintendent at Fife and Kinross Asylum, Springfield.

PHILLIPS, G. C. J., L.S.A., M.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Woburn Sands District of the County of Bedford.

RAMSDEN, WALTER, M.D., Ch.B. Oxon., has been appointed to the Johnston Chair of Biochemistry in the University of Liverpool.

WADSWORTH, T. W., M.D., Ch.B. Liverp., has been appointed Temporary Medical Officer of Health for the County of Dorset.

WEAR, A. H., M.B., B.S. Durh., has been appointed Assistant Medical Officer of Health and School Medical Officer to the South Shields Education Committee.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £150 per annum, with residence, board, and laundry.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

ACTION ON A SURGEON'S ACCOUNT.

IN the Manchester county court Professor J. W. Smith obtained judgment for £15 15*s*. and costs against Mr. A. Dasent, a clerk in the House of Commons, for services rendered. The plaintiff had been summoned at night from Manchester by telephone to attend the defendant who was on a visit to Lord Acton at Appleton Hall, a distance of 20 miles, and had gone prepared to perform an operation, which had been found unnecessary. The defendant, whose salary was £500 per annum, claimed to be prevented by poverty from paying, but had made no such suggestion when he first received the account, or, the plaintiff said, it would have been reduced. The defendant had written to say that he could not afford either to go to Manchester to defend the action or to employ a solicitor, and to ask that the claim should be heard in a London court. His honour Judge Mellor, however, observed that the defendant was able to go to Manchester to stay with Lord Acton, and found that the fee asked was reasonable.

THE "LONDON PANEL COMMITTEE GAZETTE."

To the Editor of THE LANCET.

SIR,—In reference to your comments on the "London Panel Committee Gazette," I desire as chairman of the committee dealing with the matter of over-prescribing in the county to say that neither I nor my committee had anything to do with this "surprising document." Kindly publish this, because the "document" might deter *gentlemen* from coming before the committee.

I am, Sir, yours faithfully,
Greenwich, Nov. 13th, 1914. C. W. HOGARTH.

BACILLARY AND AMŒBIC DYSENTERY.

To the Editor of THE LANCET.

SIR,—With reference to the question recently proposed in THE LANCET (Sept. 12th, p. 686) as to the diagnosis between bacillary and amœbic dysentery through inspection of the stools, it may be mentioned that Fleet-Surgeon Staby and Staff-Surgeon Kobert, of the German navy, working at Tsingtau, in China, made a report on the matter in the Blue-book on the Health of the German Navy for 1908–9, p. 61. They found that there were very few white corpuscles in the slime of amœbic dysentery, which was consequently transparent; many white corpuscles in the slime of bacillary dysentery, which is whitish and opaque. When blood is also present the slime of amœbic dysentery is clear and like raspberry jelly, while that of bacillary dysentery is a dirty brownish-red. The diagnosis can often be made with the naked eye, but the microscope further shows Charcot-Leyden crystals in the amœbic stools.

I am, Sir, yours faithfully,
W. E. HOME, M.D. Edin.,
Fleet-Surgeon, R.N. (retired.)
Victoria, B.C., Oct. 3rd, 1914.

THE "WELLCOME" PHOTOGRAPHIC EXPOSURE RECORD AND DIARY.

THE little pocket diary and exposure record, price in the British Isles 1*s*., which Messrs. Burroughs, Wellcome, and Co. have now issued for several years past, makes an excellent Christmas present for photographers, and for this reason the 1915 diary has been issued in good time. It is exactly suited to the needs of the amateur, while it contains valuable reminders for the expert photographer. Clear and simple directions are given as to the various processes of photography, and all sorts of "wrinkles" are described. Fixed inside the cover of the book is a calendar giving the necessary exposure for any time of the day or year. The book is specially ruled for the many details which the photographer requires to note. Editions are published for the northern and southern hemispheres and for the United States.

THE International Sleeping Car Company last Saturday commenced to run sleeping car services between Paris and the Riviera as far as Mentone and between Paris and Rome. Both services leave the Gare de Lyon, Paris, at 8.5. P.M. daily. From London the obviously best service to join these special services is the 10 A.M. Victoria, Folkestone, and Dieppe, arriving in Paris at 9.42 P.M., where the night must be passed, joining the special service the next day at 8.5 P.M. The company, whose offices are at 20, Cockspur-street, Charing Cross, issue tickets and advise as to hotels in Paris where passengers may stay at night. In this connexion we observe that the South-Eastern and Chatham Railway call the particular attention of passengers by the 10 A.M. train to the necessity of their heavy luggage and keys being at Victoria-station by 8 A.M. and their hand luggage by 9 A.M.

W. F.—The *Indian Ambulance Gazette* is published at Jutogh, Simla, India, monthly, price 6 annas, post free.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Sowden, Lond.; Swansea General and Eye Hospital, Secretary of; *Staffordshire Sentinel*, Hanley, Proprietor of; St. Paul's Eye Hospital, Liverpool, Secretary of; Mrs. Simpson, Nottingham; Sunderland Royal Infirmary, Secretary of: Sheffield University, Registrar of.

T.—Mrs. Thacker, Dublin.

V.—Dr. G. R. Vicars, Wood Dalling; Victoria Hospital, Burnley, Secretary of; Val-Mont Territet, Administrator.

W.—Westmorland Consumption Sanatorium, Meathop, Secretary of; Warrington Infirmary, Secretary of; Mr. W. J. Wilcox and Co., Lond.

An Address
ON
THE PATIENT AND THE DISEASE.

Being the First Hunterian Society Lecture for the Session 1914–1915 delivered in the Barber Surgeons' Hall on Oct. 14th,

By Sir DYCE DUCKWORTH, Bart., M.D., LL.D., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S AND THE ITALIAN HOSPITALS; SENIOR PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH.

Mr. President and Gentlemen,—I suppose that the name and work of John Hunter are suggestive rather of anatomy and surgery than of general medicine, but it needs no assurance from physicians to testify to the value of his influence and research on many parts of their art. We are, or certainly ought to be, as ready as the surgeons to carry in our minds his famous aphorism—"Don't think, try, be patient, be accurate." Let us consider the real meaning that this somewhat cryptic statement had for Hunter.

The Ideals of John Hunter.

Research by way of experiment was urged by him just as it had been enjoined previously by Harvey, and the problems in biology which engaged their attention were attacked by similar methods. Mere theories were to be put to the proof, and the secrets of Nature were to be exposed, if possible, and tested by the ordeal of experiment. This was to be the test of the thinking. Any inquiry necessitating research demands meditation, and to correlate the facts elicited from an experiment no less entails a large measure of thinking. Hunter clearly intended to denounce mere theory unsupported by facts. Next he urged patience. This was surely to secure further or confirmatory experiments, and a calm meditation on the results of them. There was to be no hurry or premature disclosure of the conclusions derived from early experiments. New facts were to be weighed, pondered over, and checked by repetition. Research on these lines could alone, in Hunter's opinion, lead to the last point in his aphorism—viz., accuracy or truth as its guiding principle.

It may be well for us to consider how we are carrying out Hunter's advice to-day, at a time when scientific research is more widely and actively pursued than it has ever been, so far following out his recommendation to "try" in many directions. With respect to some of these observations which bear more particularly on therapy, I venture to doubt if we are thinking or meditating adequately upon the results obtained in practice. I doubt still more if we manifest the patience which Hunter would have demanded ere we announced and urged an immediate application of some of the methods which are indicated as warrantable and safe for the treatment of the sick. The human problem is before us here, and we are on holy ground. Surely patience, meditation, and accuracy are the points we need to attend to to-day if we are to unlock the secrets of Nature, and hurry, with eager strain for results, is unseemly in such tasks. Without doubt we are naturally desirous of worthy and dependable results. The public, too, stimulated by a vulgar and debased press, is still more greedy for startling novelties of which it is keen to seek the benefit at our hands, if we are so unwise as to experiment upon them. Indeed, so keen is a section of the public, often well placed and supposed to be intelligent, in this matter that it prescribes for itself, partakes of the vaunted novelties, and becomes, alas, sometimes addicted to drug habits in consequence.

The Direction of Educated Treatment.

I have recalled to you some of John Hunter's principles. I ask you to consider the patient and the disease, and I propose to try to enforce the very plain and simple fact that when we are contemplating disease we have necessarily to consider the subject of it as well. This is not seldom lost sight of. We find books and numerous monographs written distinctly on the subject of treatment for various diseases. It appears to be forgotten that the educated physician treats *patients* and not *diseases*. It is true that many of our modern remedies which issue from the laboratory are mainly for the purpose of combating morbid conditions of the body, and when these consist of specific vaccines or sera which have the power of overcoming specific toxins, we must recognise their value apart from any special features or peculiarities of the particular patient requiring such treatment. The need for such measures is commonly urgent, and time presses for their employment—

Where the greater malady is fix'd,
The lesser is scarce felt.

Thus meningitis, diphtheria, rabies, plague, anthrax, and tetanus admit of no delay in such therapy. In the treatment (preventive) of variola and enteric fever, of syphilis, gonorrhœal arthritis, and several other septic conditions there may be less urgency, and the peculiarities of the patient may often be of minor importance and can wait.

This class of modern remedies is commonly of a specific nature, and its successful employment in many cases is rightly regarded as evidence of the scientific progress of medicine, a progress which is destined ultimately, as some believe, to abolish all empirical or old-fashioned methods of treatment. We are gradually learning to employ these agents more and more, but much remains for further clinical research and a more accurate knowledge of their action. It may be noted that vaccine therapy itself is not yet void of empiricism. Multivalent vaccines, for example, are somewhat akin to the "blunderbuss" prescriptions of a century ago, and yet they sometimes prove of value. I suppose that not a few of us are far from satisfied with the efficacy of tuberculin treatment, or of the value of pneumococcal vaccine in cases of pneumonia; and we are not without evidence that some maladies, plainly of toxic origin, are amenable to the older methods of treatment when vaccine therapy has failed to afford benefit. Amongst these may be mentioned alveolar pyorrhœa, some varieties of acne, and bacilluria. I should always prefer to begin with the older methods before resorting to vaccine treatment, and I would venture to suggest that some of us are now in danger of losing the older acquired knowledge of appropriate treatment for many common ailments.

It is, of course, a vulgar idea that medicines are employed to "cure" diseases. The homœopathic system is founded on nothing else. The charlatan treats diseases. The modern chemist prepares his proprietary compounds to cure diseases. The idea of the patient, and any of his peculiarities, receives no consideration whatever, and is supposed to be of no importance. I think that it may safely be asserted that with the progress of what we term scientific medicine, issuing largely from researches made in the laboratory, the attention of the physician has been much diverted from his patient, and directed to microbiology and biochemical matters. To state this bluntly is in no degree to minimise the supreme importance of these essential studies, but it is necessary to have a wide outlook in this matter, and to watch the outcome of it in medical practice. Modern methods certainly lead sometimes to a rapid diagnosis arrived at by bacteriology, thus yielding important knowledge by a short cut. We find that modern surgery sometimes provides a prompt diagnosis of inoperable conditions which might have been secured by patient clinical investigation without the knife.

We know well that novelties in medicine tend to obsess weak minds for a time, but some of these obsessions may be serious for the patient. To be rendered edentulous in middle life, or earlier, because of a scare of alveolar pyorrhœa which, if it exists, has not been appropriately or adequately dealt with, is surely a grave matter. To regard the large intestine as little else than a misplaced sewer and a vast source of septic mischief, necessitating its ablation on such grounds, may surely be very serious for the patient. To neglect careful examination of all parts of the body in seemingly obscure cases, and to resort promptly to bacteriological inquiries in the absence of such investigation, is hardly a wise or profitable proceeding, especially if a review of the case by thorough clinical methods readily reveals some gross disease overlooked and unsuspected. I venture to believe that in these and other ways we are tending to lose sight of the patient, and are too exclusively concerned with his disease. We are ceasing to pay adequate attention to details and to study the landmarks and varied indications of the individual patient. Our predecessors surpassed us in these methods. We have replaced them by various abstract studies bearing on disease, largely forgetful of the intrinsic interests of the individuals we minister to. Such proceedings may, perhaps, be inevitable for the present, but both patient and disease must rightly and always be considered together.

The Human Element.

In an address delivered last year[1] I expressed the opinion that practical medicine would never become a completely exact science. The human element in the case will always traverse the exactness and precision of pure science, and this factor may never be left out of account. The conception of clinical problems, and our dealings with them, necessitate an empirical element in our work if we be prudent physicians, and a large measure of that element will, as I believe, always remain to claim our careful attention and employment for the best interest of the patient. This matter relates strictly to the *art* of medicine, and it is our art that is now so much ignored and in danger of being lost. I have often remarked that a great physician is a great *artist*, and not a *savant* in the ordinary sense of that term. I would emphasise these words here and now. I suppose that the best physicians of their day have always recognised this position. It is certain, however, that many able physicians have contributed more to pure science than to the art of their profession. The father of medicine distinctly regarded his life-work as an art, and physicians as the servants or administrators of it.[2]

You may ask, What are the particular points which should be noted in patients apart from the morbid symptoms we may recognise? There are many of these. In the first place, there is a personal factor in every patient. We have therefore to discover what any particular ailment signifies to him individually. It may be well-borne or ill-borne by him. We try to ascertain his familial habit of body or specific inborn tendencies. The family history on both sides should be learned as far as possible. A history of previous ailments is important. The degree of recuperative power is found to vary much in different families. In some it is singularly slow, in others it is rapidly manifested. The measure of inherent vitality is found to vary greatly in families. That is a matter of textural or tissue resistance, and it is of singular importance to note in the maladies of aged patients.

Roughly speaking, we may readily observe the tendency to slow repair and a general vulnerability in all persons of a strumous habit of body. Such patients are bad subjects for most ailments. They heal unkindly. There is always the tendency to invasion of tuberculosis as a sequel to prolonged low health. In persons of the lymphatic diathesis we note the tendency to hyperplasia of this system, and should recognise such subjects of lymphatism as ill-fitted for anæsthesia or prolonged surgical operations. Yet in such persons we do not discover the special irritability of the lymph glands met with in strumous individuals. In patients of an arthritic habit of body we find, on the contrary, and not seldom, a large measure of resisting power with much vitality. Thus, a gouty predisposition, inherited or acquired, proves a great security against all forms of tuberculosis, and the textures are distinctly inimical to intrusion or development of tubercle bacilli in such instances. We may often note blended habits of body in individuals, as in the case of children of a gouty father and a strumous mother, the gouty element here proving a saving grace in the offspring as aiding in resisting tuberculosis, or materially checking its progress should tubercle bacilli lodge in their bodies.

It is surely obvious that our ability to frame prognoses in the illnesses of our patients is largely dependent on a careful consideration of such matters as these. To ignore them is to lead to erroneous opinions which must damage our reputation and usefulness as advisers of the public. It would reduce our powers to the level of the veterinary practitioner who is debarred largely from any consideration of such inquiries.

The Need for Clinical Observation.

I would now ask where such important knowledge is to be gained. Certainly not even in the clinical laboratory, for that is no place for gathering it. Neither will bacteriology, biochemistry, radiography, or cardiograms throw any light on the matter. Needless to remark, we need, and we value, all these modern revelations at the hands of experts, but we must avail ourselves of them as affording guides to treatment, and rest assured that by themselves they do not represent all the essentials for a successful practice of medicine. They yield no knowledge as to the personality, tendencies, and inherent textural qualities of our patients. The equipment we need in respect of knowledge of the individuals we treat is only to be gained at the bedside in daily practice. It demands great painstaking, and it occupies much time and thought. Panel practice, therefore, will accomplish little or none of it; hence our deep regret that such essential knowledge must perforce be withheld from large numbers of our worthy brethren who cannot possibly secure it in practice of that kind.

---

[1] THE LANCET, Nov. 22nd, 1913, p. 1448, Some Requirements for Modern Clinical Teaching.

[2] “ ὁ ἰητρὸς ὑπηρέτης τῆς τέχνης.”

THE INDICATIONS FOR PARTICULAR TREATMENT.

I pass now to discuss some matters relating to the treatment of patients. We do well to recognise the limitation of specific remedies and to remind ourselves that they have been discovered by simple empiricism. If we mention sulphur, cinchona, ipecacuanha, mercury, and opium we almost exhaust the list. We now know a good deal as to the nature of the specificity of each of them. Empiricism has often provided problems for laboratory research, and will continue to do so. There are few specifics for the greater number of human ailments, although we have helpful remedies to encourage recovery from most of them. We are, or might be, well-nigh distracted with the numbers of alleged specific preparations, with names far more than sesquipedalian, which are daily commended to us, mostly the products of foreign ingenuity, with attestations as to their efficacy which could alone appeal to credulous minds or novelty hunters. Yet we find that many of these are now being prescribed in preference to the approved drugs of the Pharmacopœia.

Some amongst us are keenly alive to the fact that there has been for some time past amongst us a growing disregard for our national Pharmacopœia and a spreading ignorance of its formulæ. I venture to regard this as a serious matter, for it represents a lack and contempt of knowledge which is essential for success in practice and the real welfare of the patient. I fear there are few amongst us to-day who will thus openly express such an opinion, but I will place mine on record. Many of our prescriptions are now laughing-stocks for well-educated pharmacists who have to compound them, and they must wonder at our boldness and our credulity. I am very sorry for the patients of such prescribers. I need hardly remark that we duly note the progress of pharmacy in various directions, and the improvements in many of our formulæ in the Pharmacopœia. We could wish that the pharmacists were less occupied with the distracting novelties I have referred to, and could thus give their time and attention to more important matters of real pharmaceutical interest.

Opinions emanating from the chemical and other laboratories, non-clinical, are not always helpful to us as careful practitioners. Take the case of alcohol as a remedy. We are told that it is a poison and a devitalising agent, and that it has no place for use either in health or disease. The observant clinician, on the contrary, finds it to be extremely useful for the patient. We always knew that in certain doses it was poisonous, but we also knew that persons who used it in strict moderation lived their full term of life, and left no signs of any lesions in their body, which could honestly, and exclusively, be attributed to alcoholic influence. A physician is not a pure chemist, nor is he a pure physiologist. The tolerance for certain drugs is found to vary largely in different patients. Apart from pure idiosyncrasies, the beneficial effects of mercury in the dark-skinned, bilious, and arthritic subjects, and its less satisfactory action in the fair and strumous ones are hardly recognised to-day. Saline aperients are supposed to take its place in the former class, and mercury is now inadequately employed, or with timidity, for many patients. Not many of us have been taught, or have acquired, a knowledge of the value of sarsaparilla in large doses as a restorative remedy in many cachectic conditions. The influence of musk in sometimes turning the scale favourably in perilous conditions of pneumonia is not recognised to-day. These drugs have actually been discarded from the new Pharmacopœia about to be issued. Happily that will not prevent their employment. Our observant predecessors noted these matters, but their teaching has been forgotten or displaced. It did not issue from the laboratory, but from careful observation at the bedside and in daily practice. In regard to the use of opium, I think that we have parted with a good deal of experience bearing on its appropriate use by the mouth in many morbid states, and have come to rely too much upon one of its constituents introduced by way of the hypodermic syringe. Again, with respect to the virtues of cinchona, I think that we lose some of them by selecting so rigidly only one of its constituents for constant use.

The art of prescribing is not limited to mere convenience and rapidity of dispensing. The active principles of some drugs do not always represent the full benefits of the source of them. Those of us who have been trained in our great hospital schools know well the value of many of the formulæ set down in their pharmacopœias. They are always worthy of our regard, because they represent the experience of our observant masters who introduced or adopted them solely on account of their usefulness and power to aid recovery. Generations of their pupils have had good reason to discover this for themselves. There is no fashion or novelty in them, and many of them will, as I believe, be found helpful for all time. I have long been impressed by many of the prescriptions thus employed in the Dublin schools of medicine which have passed down from some of their great clinical masters, and still secure the confidence of their successors.

THE VALUE OF SYMPATHY.

In the best interests of the patient it is necessary for the physician to learn the art of skilled nursing as practised in these days. If he does not understand the details of this service he cannot be competent to direct the nurses who work under him. These duties can be best learned in hospitals with well-disciplined nursing schools, and it should not be neglected or ignored by the clinical clerks and dressers. It was said of one of our greatest clinicians at one time that he was equally able as a physician or as a nurse. Many of us, I doubt not, could testify to the useful teaching we have had from our hospital matrons and sisters.

We may never forget that what is termed the humanity of our profession relates not merely to kindness, gentleness, and sympathy. Our duties must take note of the specially human characters and varied peculiarities of the individuals we treat. This concerns very largely the management of patients, a great clinical art and equipment. We begin our professional work by studying Nature in all her forms, and, as Charles Kingsley remarked, "if we do not know Nature we cannot know Art."

TRUE PROGRESS.

Some of my remarks may lead you to regard me as a strange survivor of the early nineteenth century physicians, and my opinions as little available for the practical duties of to-day. I will, however, venture to remind you that real progress does not consist in wiping out the past. That idea comes from Germany. A prudent veneration for the best of what has been left to us is ever a wholesome sign of the minds that are to guide the future. Well-gathered experience will always count for much in practical medicine. Knowledge that comes too quickly and too copiously has often to be recast and modified, and the elders do good service sometimes by calling a halt for meditation, for open minds and level heads. Moderation is one of the few things that last long in this world.

Scepticism, pure and simple, never won, and never will win, anything in practical medicine, but it has led in time to wider views and a more sane comprehension of its difficulties. Credulity has been well-nigh as harmful, and it leads nowhere. As has been well said, "the wide man is the great man." There can be no narrowness in our art. So we come back to John Hunter and his methods, for we need to labour on by the light which they will ever afford. We have far greater difficulties to meet in our daily duties than fall to the lot of other workers, because we are dealing with our fellow man, an immortal soul-bearing human creature, more complex and strange than any other created being. The physician may never lose sight of this great fact, and it places him on a separate platform from that occupied by any other students of science. Ours is indeed the most human of all the professions. As I have already remarked, we welcome help from all sources of accurate knowledge conducted by experts, especially from those possessing clinical opportunities, and we must receive with caution the teachings which emanate from sources where work is carried on less for absolute accuracy than for gain or mere notoriety. We know well that medicine cannot stand still, for it is essentially a progressive art. Our motto should be "*Ausculta et perpende.*"

I have now only to ask you to consider any of my opinions in the spirit in which I have ventured to present them to you. My sole object has been to set before you what I humbly conceive to be the true relations which we ought to recognise in our practice between the patient and the disease. We must never lose a full consideration for the patient in any effort we make for his welfare and recovery, and we can have no fear that careful scientific progress and observation will fail to add to the perfection of our art.

EDINBURGH MEDICAL MEN AND COMPULSORY MILITARY TRAINING.—A discussion on Compulsory Military Training as it Appears to the Medical Profession was opened by Professor W. Russell at a meeting of the Scottish Medical Guild held in Edinburgh, on Nov. 13th. A motion was proposed that in the opinion of the meeting compulsory training was highly desirable in the interests of the physical and moral welfare of young men and for our national security, and that at the present juncture the members of the medical profession as represented at that meeting should undertake to do what lay in their power towards its attainment. Dr. Graham Brown seconded this motion, and said that we were the only nation in Europe whose men hired other men to fight for them. That was an unfair and undemocratic arrangement, because no man who was physically fit for service should be able to escape service. The proposition was unanimously adopted.

OBSERVATIONS ON MYELOID SARCOMA, WITH AN ANALYSIS OF 50 CASES.*

BY MATTHEW J. STEWART, M.B. GLASG.,
M.R.C.P. LOND.,
CLINICAL PATHOLOGIST, LEEDS GENERAL INFIRMARY; HONORARY DEMONSTRATOR IN CLINICAL PATHOLOGY, UNIVERSITY OF LEEDS.

THERE is perhaps no subject in the whole range of surgical practice where the coöperation of surgeon and pathologist is more necessary than in the case of myeloid sarcoma. Not only the extent of the operation but the ultimate prognosis depends finally on the histological diagnosis, although in most instances it is possible to say, from the naked-eye characters alone, whether or not one is dealing with a case of this kind. On the other hand, a perusal of the literature shows that errors in diagnosis may be made even where the growth is submitted to microscopic examination, and this is generally due to mistaking a malignant giant-celled for a myeloid sarcoma. Although it is the usual teaching nowadays that these growths (myeloids) are of very low malignancy, there still seems to be an unwillingness on the part of many surgeons to treat them by local excision, and this is undoubtedly due, as already indicated, to the fact that in the past cases of so-called myeloid sarcoma have been reported in which death with visceral dissemination occurred at a longer or shorter period after operation.

The purpose of the present communication is to emphasise the importance of distinguishing true myeloids from other giant-celled sarcomata, to advocate conservative treatment of such cases, and to indicate the histological criteria by which the microscopic diagnosis may be made. My remarks are based on an analysis of all the cases of myeloid sarcoma, 50 in number, treated at the Leeds General Infirmary during the years 1899 to 1912 inclusive. These have been investigated from both the clinical and the pathological standpoint, but special attention has been paid on the one hand to the question of prognosis, and on the other to the minute anatomy of the growths. Much of the confusion which at present exists with regard to these tumours must be attributed to different observers employing the same words to denote different things. Thus from a study of the literature it is clear that by some authors the term myeloid sarcoma is used to indicate any form of sarcoma in which giant cells occur in large numbers, while by others it is restricted to the class which I am now describing. It will be well, therefore, at this point to define precisely the terms to be employed in the present communication.

Giant-cell sarcoma is used in its widest sense as a term to include all sarcomata in which giant cells of blastomatous origin constitute an important, it may be the essential, feature of the microscopic picture. This large class is made up of two groups of cases: (1) the *myeloid sarcomata*, myelomata of some authors; and (2) the *malignant giant-cell sarcomata*. Probably the bulk of the latter could be described alternatively as polymorphous cell sarcomas containing giant cells, especially as one can usually find cells of all sizes, from the smallest to the largest; but in a certain number of cases the giant cells are so abundant and so striking that the employment of a special term, malignant giant-cell sarcoma, seems not only warranted but desirable. In order to obtain data for comparison I have traced five examples of this latter type of growth, and the difference in the clinical history of the two groups of cases is rather remarkable. My reasons for preferring the term "myeloid sarcoma" to "myeloma" I shall refer to later.

---

* A paper read at a meeting of the Leeds and West Riding Medico-Chirurgical Society.

Current views on myeloid sarcoma.—Before proceeding with the analysis of cases I propose to review briefly some of the more recent authoritative opinions on this subject. With regard to prognosis Bland-Sutton[1] states quite unequivocally, "Myelomata do not infect lymph glands nor disseminate"; and, again, "A close study of the myelomata indicates that they differ histologically, pathologically, and clinically from sarcomata, with which they have hitherto been grouped." In a discussion at the Royal Society of Medicine on myelomata and sarcomata of long bones in December, 1912, the same author says,[2] "No one will deny that the separation of myeloid tumours from sarcomas has been justified by experience, and many useful limbs have been saved in consequence." In America Bloodgood,[3] of Baltimore, is an ardent exponent of the same view; and he has from time to time adduced important evidence in support of the conservative treatment of such cases. In a paper read before the American Surgical Association last year he states: "Up to the present time we have no proof that the pure giant-cell sarcoma ever metastasises. It is a question, therefore, whether it should be called a sarcoma." Eve[4] thinks that the malignancy of myelomata is partly dependent on their situation—e.g., he says: "The broad general statement made in some text-books that the myelomata are only locally malignant requires ...... considerable modification. The myelomata of the femur, and especially those of the upper end of the humerus, are sometimes followed by metastasis. ...... The nearer the body the greater the malignancy would appear to be true of the myelomata as well as of the periosteal sarcomata." He adds, however, "I suspect that the old statistics have been made less favourable by the inclusion among myelomata of a certain number of round- and spindle-celled tumours containing a few multinucleated cells such as are present in many rapidly growing neoplasms."

While strongly in favour of the view that true myeloid sarcoma is only locally malignant, in which respect it is analogous to rodent ulcer, I see no reason why it should not occasionally undergo sarcomatous transformation, as happens in the case of other benign connective tissue growths. To continue the above analogy, it would be on all fours with the development of epithelioma in a rodent ulcer, a well-attested clinical and pathological fact. This is the view expressed by Adami,[5] who says, "It does not form metastases, save in the infrequent cases in which it undergoes sarcomatous modification." Sims Woodhead[6] regards the tumour as essentially a spindle-celled sarcoma from the outset, and thinks the giant cells owe their presence to a mere accident of position—viz., in relation to a bone.† He says also, "The typical form seldom gives rise to secondary growths, but secondary tumours when found in the position ordinarily affected contain no giant cells; they are simply small spindle-celled sarcomas." Mallory[7] goes yet farther and regards the giant cells merely as so many foreign body giant cells. Yet other authors hold that myeloid sarcoma may give rise to metastatic deposits having a structure identical with that of the primary growth, and in the discussion at the Royal Society of Medicine Maybury[8] referred to two recent cases which he regarded as supporting this view. In the first of these the primary growth was in the lower end of the femur, and the limb was amputated through the upper third of the thigh. Death took place nine months later. In the second case the primary growth was in the innominate bone, and the patient, who was too ill for operation, died a month after admission. In both cases secondary deposits were present in the lungs, their nature being determined post mortem by microscopic examination. Through the kindness of Dr. Leonard Dudgeon I have been enabled to examine the slide from the growth of the femur in the first of those cases, and in my opinion it is not a true myeloid but a malignant giant-cell sarcoma. This is borne out by the results of the microscopic examination of the lung nodules, undertaken by Mr. W. Gough, the patient having died in the North Ormesby Hospital, Middlesbrough. His report is as follows: "In section, the tumour is a mixed-cell sarcoma. Most of the cells are spindles, but some irregular, round, and giant forms are found." I have not seen the sections from the second case, but the microphotograph suggests a mixed-cell sarcoma with giant cells (malignant giant-cell sarcoma) rather than a true myeloid.

Analysis of Cases.

In every one of the 50 cases here recorded the diagnosis has been confirmed or made by microscopic examination of the tumour, and in 45 I have personally verified the pathologist's report. A systematic account of the gross morbid anatomy has been omitted, as only a very few of the actual specimens have been preserved.

Situation and frequency.—Of the 50 cases, 35 are from the jaws, 11 from the long bones, and 4 from other situations. This represents roughly an average of one long bone case and three jaw cases annually, since the total figures correspond to a period of 14 years. When one considers the number of surgical cases dealt with every year in the Leeds Infirmary, it is seen that the disease is relatively an uncommon one. The situation in 26 out of the 35 jaw cases is shown in the following: Upper jaw, 12; lower jaw, 13; both jaws, 1. The uniformity of incidence in the two jaws is remarkable. The latter case, which will be referred to later, is the only example in the whole series of a multiple lesion; in it there was one growth in the upper jaw and two in the lower.

The following shows the incidence in other bones: Femur, 6 (4 lower end and 2 upper end); humerus, 3 (2 lower end and 1 upper end); metacarpal, 3; tibia, upper end, 1; radius, upper end, 1; and coccyx, 1.

These figures are in rather striking contrast to Bland-Sutton's dictum, that the tibia is the favourite bone in the lower limb, the radius in the upper, but they are clearly far too few to warrant generalisations. In order to obtain data of greater significance I have added the 11 long bone cases of my series to 10 long bone cases collected by Gask[9] from St. Bartholomew's Hospital records—viz., those occurring during the ten years 1902 to 1911—and to 12 similar cases collected by Maybury[10] from St. Thomas's Hospital records—viz., those occurring during the 11 years 1901 to 1911. All these are cases which have been verified microscopically. The result is shown in the following: Femur, 19 (17 lower end and 2 upper end); tibia, 5 (all upper end); humerus,

---

† A similar view is expressed by Hamilton, Text-book of Pathology, 1889.

4 (2 upper end and 2 lower end); radius, 4 (3 lower end and 1 upper end); and fibula, 1 (upper end).

It is a very striking fact that out of these 33 cases in more than half the disease was situated in the lower end of the femur; but the fallacy of generalising from a series such as this is well shown by comparing these figures with the cases reported by Bloodgood.[11] Here, in 10 cases out of 18, the tumour involved the lower end of the radius.

Age and sex incidence.—The age was ascertained in 49 cases, and the results may be shown in tabular form as follows:—

—	Long bones, &c.	Jaws.	All cases.
Under 10 years.	—	7	7
10–20 ,,	—	11	11
20–30 ,,	6	7	13
30–40 ,,	5	4	9
40–50 ,,	3		8
50–60 ,,	1	—	1

The table shows that myeloid sarcoma tends to occur at a somewhat later age in the long bones than in the jaws. In this series the average age at the time of operation was, in the former, 34 years, in the latter 20·6. Taking all cases together, we see that the disease occurs with singularly uniform frequency in each of the first five decades of life, and that above 50 it is exceedingly rare. If the two varieties be studied separately it is seen that in the case of the long bones the disease is most common between 20 and 40, while in the case of the jaws the greatest frequency is in the second decade. In the long bone cases the youngest patient was 21, the oldest 51; in the jaw cases, 5 and 50 respectively. Bland-Sutton states: "The patients are young, rarely above 25 years of age." In this series of 49 cases, 24 only were under that age, while of the 15 long bone, &c., cases, 2 only were under 25. The sex was ascertained in 48 cases, of whom 18 were males and 30 females. In the long bone cases there were 6 males and 9 females; in the jaw cases 12 males and 21 females.

Clinical course, treatment, and after-history.—In the first place I shall consider those cases, 15 in number, where the disease occurred in other bones than the jaws. Of these, 11 have been successfully traced. The duration of the disease at the date of the first admission was ascertained in 14 cases, 2 of whom gave a history of two and three years respectively, while the rest varied from one month to 15 months. The average for the series was 10½ months. Pain was the initial symptom in 6 cases, and in 5 of these it was subsequently followed by swelling. In 6 cases also swelling was the first clinical manifestation, and was followed by pain in two instances. In 2 cases pain and swelling appeared at the same time, while *functio laesa* was present in 3 cases only. In one case the patient was admitted with a spontaneous fracture at the site of growth. A history of injury was obtained in 6 cases, including one where there had been a spontaneous fracture at the site of the tumour three years before. In no case did the tumour attain a very large size, nor did fungation occur, save in one untreated case. Egg-shell crackling was elicited in one case, but only after the bone had been exposed at operation. In Case 13, where the upper end of the radius was involved, the lesion presented the naked-eye characters of a bone cyst, but on microscopic examination a narrow layer of typical myeloid tissue was found lining the bony wall. Case 1 was originally diagnosed and treated as a chronic synovitis of the knee. Radiographic examination was undertaken in 3 cases, and materially aided in the diagnosis.

From the point of view of treatment, many interesting and several highly satisfactory results were obtained. The cases may be divided into two categories—viz., those in which conservative measures were adopted in the first instance, and those in which amputation of the affected limb was carried out as soon as the diagnosis had been made. It may be stated at once that out of 11 cases traced 9 are alive and well at the present time, in 1 the disease has recurred, and 1 only is dead. The latter was a man, aged 49, with myeloid sarcoma of the upper end of the femur, who refused operation, and in whose case the diagnosis was established by exploratory incision and removal of a small portion of the growth. The patient lived for five years thereafter, the growth ultimately fungating in several places, but there was never any clinical evidence of metastasis. Seven cases were treated by local removal of the growth and 7 by immediate amputation; of the latter, the 4 cases traced are now alive and well. They include 2 femur cases treated by amputation through the thigh, and two humerus cases, one treated by interscapulo-thoracic amputation, the other by a mid-arm amputation. Of the 7 cases treated by local removal of the growth together with a greater or smaller margin of healthy bone, 3 were cured and 3 recurred; the seventh was not traced. Of the 3 which recurred one was cured by a subsequent local removal and one by amputation; the third has recurred at the time of writing. Inasmuch as the greatest interest and importance attaches to those cases in which conservative treatment was attempted, it will be instructive to consider them a little more fully.

Perhaps the most striking result in the whole series was that obtained in Case 7 by Mr. H. Littlewood. The tumour in this instance involved the upper end of the right femur, and had led to considerable expansion and thinning of the great trochanter. An incision was made over the latter, and a scraper forced through the expanded shell of bone. Masses of soft friable growth were thus removed, and the tumour was found to extend up the neck to the head and down the shaft as far as the lesser trochanter. There was no evidence of joint involvement. All the growth was scraped away until a hard, smooth wall was obtained, the cavity being packed with gauze. When the patient was dismissed five weeks later the wound was quite healed. Now, seven years later, the patient is alive and well, with a limb which is so sound and useful that he is able to follow laborious employment in an iron foundry. In Case 13 Mr. R. L. Knaggs, five years ago, resected the upper part of the left radius for a myeloid tumour, with completely satisfactory results. In Case 12 Mr. J. F. Dobson excised a myeloid sarcoma of the lower end of the humerus, together with a margin of healthy bone. The patient is now, 18 months later, alive and in good health, but has still some limitation of movement at the elbow-joint.

The following are brief notes of the three cases in which local removal was followed by recurrence. Case 9 is an interesting example of myeloid sarcoma of the coccyx, a condition to which I have been unable to find any reference in the literature

The patient, a married woman, aged 27, was first admitted under the care of Mr. E. Ward in March, 1907, complaining of a small tense tumour over the coccyx, first noticed some five months before. On rectal examination the mass was found to be much more extensive than appeared on the surface. At operation on April 12th the tumour was found to arise from the coccyx and to be infiltrating the surrounding tissues to a marked extent. The diseased parts were freely excised, and the patient was dismissed well on May 11th. In January, 1909, nearly two years later, the patient was admitted under the care of Mr. W. Thompson with recurrence *in situ*, and an extensive removal of the growth was again undertaken. The patient is now in excellent health, and since her second operation has given birth to two healthy children. In Case 11 the disease involved the upper end of the right tibia. On Sept. 30th, 1907, a skin flap was raised and the growth scraped away until hard bone was reached all round. Four months later the patient was admitted with recurrence in the old site, and a further attempt at local removal being rapidly followed by a further recurrence, the limb was amputated above the femoral condyles. In Case 6 the disease was situated in one of the metacarpal bones, which was excised. Now, nine years later, there is evidence of local recurrence, which first manifested itself about two years ago. The patient in the meantime refuses to have further operative treatment, so that histological proof of recurrence is lacking. It may be stated here that so far as it is possible to judge from the notes, all the long bone cases were of the endosteal type, while all the jaw cases, with one possible exception, were of subperiosteal origin.

I shall now refer very briefly to the jaw cases, 35 in number, 29 of which have been successfully traced. The duration of the disease was stated in 14 instances, and varied from two months to five years, the average being 16 months. The disease was attributed to trauma in 2 cases only; in Case 20 it was alleged to have followed a tooth extraction which had taken place six months previously, while in Case 39 the patient ascribed the onset to the irritation of an artificial denture. In every case where notes are available the tumour took origin from the alveolar border of the jaw, from which it usually projected as a small plum-coloured nodule. The method of treatment varied from removal with scissors or scraping away to complete excision of a portion of the lower jaw, which was performed in one instance. In the great bulk of the cases the small portion of alveolar margin from which the tumour arose was excised with the growth. Of the 29 cases traced recurrence took place in 4, and in 3 of those a cure was effected by subsequent local removal; the remaining case is dead. The latter was a boy aged 12, the subject of some obscure bone affection, who died two years after the removal of three myeloid sarcomata from his jaws. His case, which is one of very great interest, will be published in full by Mr. Lawford Knaggs, and I need only mention here that although there was local recurrence in the jaws he never presented any clinical evidence of metastasis. Indeed, for a year before death he was profoundly asthenic and bedridden. Microscopically all three jaw tumours presented the typical characters of myeloid sarcoma, and each appeared to be quite independent of the others.

The most striking feature, to my mind, of this series of myeloid sarcomata is that out of 40 cases traced 38 are alive at the time of writing, and in one only is there now recurrence. The patients have been under observation for periods varying from 1 to 14 years, and 31 out of the 40 cases traced are of over three years' standing. Of the 2 cases dead, 1 had refused operation and lived for five years thereafter, ultimately becoming bedridden with a fungating tumour of the thigh; the other, the case just described, died really from an independent affection. There is no evidence that dissemination took place in either case. In the light of these results the ultimate prognosis in cases of myeloid sarcoma, after efficient removal of the growth, can only be regarded as highly favourable.

Malignant Giant-cell Sarcoma.

While collecting the material on which the preceding analysis is based, I took the opportunity of examining the microscopic specimens from all cases of sarcoma of bone investigated in the pathological department of the Leeds General Infirmary during the period under review. From amongst these I have collected five examples of malignant giant-cell sarcoma, to which I have added a sixth examined in private some two years ago. One of the cases has not been traced, and is consequently useless for purposes of comparison from the clinical standpoint. In the other 5 the situation of the growth was as follows: tibia, upper end, 2; femur, lower end, 2; and jaw, 1. All four lower limb cases were treated by amputation through the upper part of the thigh; the jaw case, having been diagnosed as a "myeloma," was treated by local excision. The histological characters, which contrast markedly with the myeloid series, will be referred to later.

The after-history is very striking. In every one of those 5 cases the disease proved fatal in from six months to three years from the time of operation, and in each of the four long-bone cases there is a clear history of lung metastasis. Post-mortem verification of this, however, was obtained in one instance only. None of the cases had recurrence *in situ*. In the jaw case I have been unable to obtain an accurate account of the final illness. It is to be noted that four of those cases were determined to be examples of malignant giant-cell sarcoma from the microscopic appearances only, and before the after-history had been ascertained. In the fifth I had occasion to examine only the secondary lung deposits, but by the kindness of Professor Eurich I have been able to examine also the slide of the primary growth. It is thus seen that from the clinical standpoint the contrast to the myeloid series is most marked, showing how very important it is to be able to say, from the microscopic characters, whether a given growth is a true myeloid sarcoma or not.

Histopathology.

The distinctive feature of a myeloid sarcoma is its giant cells. These vary greatly in number in different cases and in different parts of the same tumour, but, except for their apparent variability in size and in number of nuclei, they are remarkably constant in their morphological characters. The "matrix" of the tumour, on the other hand (if one may be allowed to use the term), shows great variation in different cases. It may be exceedingly fibrous or very cellular, and it may be spindle celled, round celled, or mixed celled. As a rule, the more rapidly growing myeloids have a round- or mixed-celled matrix, while the more slowly growing are spindle celled. The former also are richly cellular, while the latter tend to be increasingly fibrous. The relative proportion of giant cells and stroma is determined chiefly by the situation of the tumour, but also bears some relation to the rate of growth. Periosteal myeloids, which arise usually if not invariably from the alveolar margin of the jaws, are characterised in most instances by an abundant spindle-celled or fibrous matrix with relatively few giant cells, while the soft, maroon-coloured, endosteal myeloids of the long bones have numerous giant cells, and a much less abundant stroma. As a rule, also, the more rapidly growing tumours contain an abundance of giant cells irrespective of their site of origin, and they are traversed by numerous thin-walled capillary blood-vessels, often of considerable size. These differences in the minute anatomy explain the different appearances found naked eye—namely, the firmness and small size of the great majority of jaw myeloids, and the softness and proneness to degenerations and hæmorrhages in the rapidly growing endosteal myeloids of the long bones. In jaw myeloids especially the essential tissue of the tumour is frequently broken up into small masses by broad bands of fibrous tissue, and these, as well as the matrix generally, are often the seat of large deposits of golden-yellow pigment, probably a derivative of effused blood. In the deeper portions of jaw myeloids small bony spicules are often present, more or less closely connected with the subjacent bone. In jaw cases also, when the growth attains a certain size, the epithelial and periosteal coverings disappear and their place is taken by a narrow granulation-tissue zone, the surface layer of which is usually necrotic.

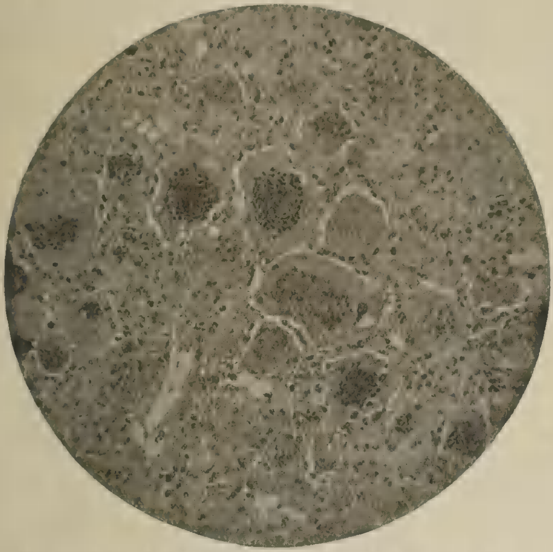
The giant cells of myeloid sarcoma (Fig. 1 and Fig. 3, A) closely resemble the osteoblasts and osteoclasts of normal bone, but they frequently attain a very much larger size and may exhibit a whorled arrangement of the nuclei which, I believe, is characteristic. They do not resemble the myeloplaxes or mononuclear giant cells of the bone marrow, as stated by some authors. The cytoplasm is usually abundant, especially at the periphery, and presents a homogeneous ground-glass appearance. Vacuoles, mostly peripherally situated, are often present and may be of large size, when they not infrequently contain cell inclusions. The nuclei are uniformly small in size, and where not closely packed together are round or oval in shape. They stain intensely with the basic dye and usually contain a single nucleolus. After careful search I have been unable to determine the occurrence of mitotic nuclear division within the giant cells, even where mitotic figures were present in abundance in the cells of the matrix. The number of nuclei, and consequently the size of the cell, varies immensely in different cases. In most periosteal jaw myeloids the giant cells are comparatively small in size, and contain, in a given section, from 12 to 40 nuclei. In endosteal myeloids, on the other hand, they are larger on an average, and may attain a very great size. In cells of the latter class I have frequently counted upwards of 200 nuclei in a single section. In the smaller giant cells, and in many of the larger, the nuclei are uniformly distributed throughout the cytoplasm, but in certain of the latter they are grouped in the centre, and many exhibit the whorled arrangement already referred to. It is when the nuclei are thus packed tightly together that they lose their usual round or oval shape and become irregularly polygonal from mutual pressure. The peripheral ring-like distribution of nuclei so characteristic of tuberculous giant cells is practically unknown in cases of myeloid sarcoma. A point to which I wish to draw special attention is that there are no transitional forms between the giant cells and the other cellular constituents of the growth; all cells can be relegated with certainty to one class or the other.

It will be convenient now to contrast with these the histological characters of malignant giant-cell sarcoma. The stroma, as in the case of myeloid sarcoma, may be round, spindle, or mixed celled, and, as in it, the number of giant cells varies greatly in different cases and in different parts of the same growth. The cells of the stroma are much more irregular as a rule, and it is always possible to find transition forms from the smallest to the largest. A striking feature is the large size and irregular shape of many of the nuclei. Mitotic figures, many of them irregular, occur with great frequency both in the giant cells and in the cells of the matrix. As these are not infrequently cases of chondrosarcoma and osteosarcoma, cartilaginous or bony islets may be met with, in the secondary deposits as well as in the primary growth. It is the giant cells, however, and especially their nuclei, which constitute the chief distinguishing feature of this group. (Fig. 2 and Fig. 3, B, C, D, and E.) Here the nuclei are extremely irregular in size and shape, often presenting lobes and indentations, while most of them are of large size. Not infrequently nuclei of enormous size are met with, and in such cases the giant cell may be mononuclear. The number of nuclei seldom exceeds 6, and most of the cells possess from 1 to 4 only. They usually lie clumped together in the cell, so that often it is difficult to determine precisely how many are present. Mitosis within the giant cells is of common occurrence, and very frequently this is of the multipolar type, an event which may in itself account for the presence of multiple or multi-lobed nuclei in these cases. It is to be noted that mononuclear giant cells and mitosis of giant-cell nuclei, common in the malignant type, do not occur in myeloid sarcoma, while vacuolation of the cytoplasm, common in the latter, is rarely seen in the other variety.

A word must be said as to the occasional occurrence in small numbers of osteoclast-like giant cells in cases of malignant giant-cell sarcoma. These probably originate in the adjacent abnormally stimulated bone, and are of no special significance. That the giant cells of myeloid sarcoma are neoplastic there can, I think, be little doubt. Mallory[12] has recently advanced the view that they are of the nature of foreign body giant cells, in which category he places also the osteoclasts themselves. To such a view many serious objections may be brought forward. While osteoclasts may possess, in part, some of the functions of foreign body giant cells, they are at the same time essential constituents of normal bone, and it is still a moot point whether the same cells may not become, under certain conditions, bone-builders instead of bone-destroyers. I would therefore lend my support to the view expressed by Adami [‡] that the giant cells of myeloid sarcoma are to be regarded as specific constituents of the tumour and not as a mere accidental feature dependent on the situation of the growth. If they are foreign body giant cells how are we to account for their presence in such large numbers in the case of myeloid sarcoma, and their fewness or actual absence in other sarcomas of bone? There is this other point, that irritation or foreign body giant cells, when these occur in response to known stimuli, have a definitely focal arrangement, even where they are present in very large numbers, therein differing markedly from the giant cells of myeloid sarcoma. Finally, there is the central whorled arrangement of nuclei already mentioned, an appearance which, so far as I am aware, is quite unknown in the case of foreign body giant cells.

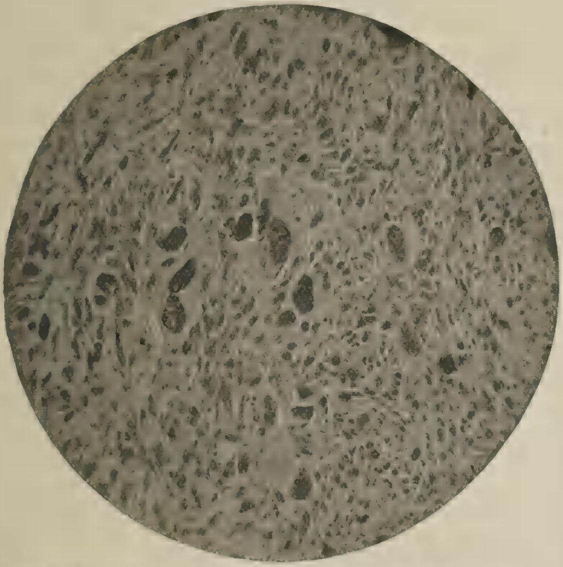
[‡] Adami advances arguments against Mallory's contentions in a footnote to his article on Myelomas. Text-book of Pathology, vol. i., p. 734.

FIG. 1.



Microphotograph of a typical endosteal myeloid sarcoma. The whorled arrangement and uniform character of the giant-cell nuclei, and the vacuolation of the cytoplasm are well shown. (From Case 15. $\frac{1}{4}$ inch objective, without ocular.)

FIG. 2.



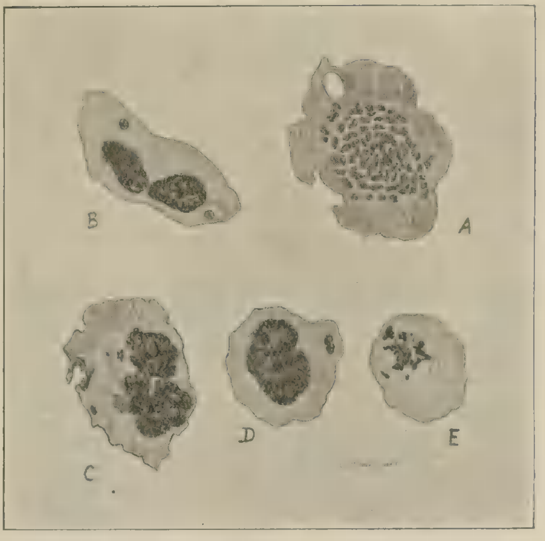
Microphotograph of a malignant giant-cell sarcoma from the lower end of the femur. The nuclei of the giant cells are large, irregular, and few in number. ($\frac{1}{4}$ inch objective, without ocular.)

Myeloid Tumours of Tendon-sheaths.

This is a rare condition to which French writers especially have drawn attention. In these tumours, which arise chiefly from the synovial sheaths of the flexor tendons of the hand, typical myeloid giant cells are present in considerable numbers, and yet, as a rule, there is no evidence of any bony connexion. The bulk of the tumour is made up of round and spindle cells with a good deal of fibrous tissue, but in some cases at least the structure is markedly alveolar, the tumour cells are polygonal, and the whole appearance suggests endothelioma. This is the view taken by Bellamy,[13] who regards the giant cells as formed by the fusion of the smaller (endothelial) cells of the growth, and suggests the use of the term "myeloid endothelioma." My own experience is limited to a single example, but as this did not occur in a hospital patient it has been omitted from the present series.

Throughout this paper the term "myeloid sarcoma" has been employed in preference to the more modern "myeloma," for the reason that I still regard the tumour as essentially embryonic in structure, whether it be looked upon as arising from bone or from bone marrow. In the more slowly growing members of the group there is certainly considerable formation of fibrous tissue, but the same is true of many other sarcomata (fibro-sarcomata). The tumours, moreover, exhibit undoubted evidence of local malignancy, as shown by their power of erosion and by their lack of definition at the periphery. I have already compared them to rodent ulcer, among epithelial growths, in respect of many of their clinical characters, and this is an analogy which might profitably be borne in mind by the surgeon.

FIG. 3.



A, A typical myeloid giant cell. The nuclei are numerous, small and regular; they are centrally situated and exhibit a whorled arrangement. B, C, D, E, Giant cells from four of the cases of malignant giant-cell sarcoma mentioned in the text. The nuclei in B, C, and D are large, irregular, and few in number; in E there is a multipolar mitotic figure. These five cells measure approximately 123μ, 116μ, 108μ, 79μ, and 69μ respectively in long diameter. (Drawing by Miss E. M. Wright.)

Summary of Conclusions.

Myeloid sarcoma is locally malignant only and does not undergo dissemination. It is to be clearly distinguished, both clinically and pathologically, from malignant giant-cell sarcoma, in which death with visceral dissemination is the rule, even after the most radical operative treatment. The histological diagnosis is based on the morphological characters of the giant cells, especially as regards their nuclei. In myeloid sarcoma the latter are numerous, uniform, small, and without mitoses; in malignant giant-cell sarcoma they are few, sometimes single, irregular, and often very large, while mitotic figures are frequent. After investigating this comparatively large series of cases, and from a study of the literature, I feel bound to advance a strong plea for the conservative treatment of myeloid sarcoma. Especially would I advocate thorough curettage as the operation of choice in the first instance in suitable cases; failing this, a local resection of the growth. Amputation should be the last resort, and only after the failure of less radical measures. An accurate histological investigation of the tumour is in all cases essential.

I wish to express my great indebtedness to the honorary surgical staff of the Leeds General Infirmary for their kind permission to make full use of their cases.

Leeds.

HEART-BLOCK IN ACUTE RHEUMATIC CARDITIS.

BY A. E. NAISH, M.A., M.B. CANTAB., M.R.C.P. LOND., M.R.C.S. ENG.,
SENIOR ASSISTANT PHYSICIAN, SHEFFIELD ROYAL HOSPITAL;
AND
ALEX. MILLS KENNEDY, M.D. GLASG.,
ASSISTANT TO THE MUIRHEAD PROFESSOR OF MEDICINE, UNIVERSITY OF GLASGOW; DISPENSARY PHYSICIAN (LATE ASSISTANT PATHOLOGIST), GLASGOW ROYAL INFIRMARY; PATHOLOGIST TO THE GLASGOW MATERNITY AND WOMEN'S HOSPITAL.

THE occurrence of heart-block in acute disease is now well recognised. It is known to occur in influenza, typhoid fever, pneumonia, diphtheria, rheumatic fever, and ulcerative endocarditis, but hitherto comparatively few post-mortem reports on such cases have been published.

In 1908 Jellinek and Cooper[1] reported a case of complete heart-block in acute gonorrhœal endocarditis dependent upon an acute necrosis of the interventricular septum; in another case of ulcerative endocarditis (James[2]) an ulcer of the interventricular septum immediately beneath and posterior to the membranous septum was the cause of the block; in Gerhardt's case[3] of rheumatic fever, followed quickly by enteric fever, inflammatory lesions were found in the a.-v. bundle. In 1910 one of us (A. M. K.[4]) recorded the presence of acute inflammatory cellular lesions in the a.-v. bundle in a case of acute endocarditis with partial heart-block, and a case of complete heart-block in diphtheria[5] in which acute inflammatory cellular lesions involved the a.-v. node and bundle; and in the same year Magnus Alsleben[6] reported a case of heart-block in diphtheria dependent upon a severe parenchymatous degeneration of the a.-v. bundle. A year later Butterfield[7] recorded a case of acute carditis with partial heart-block existing for 11 days before death. In this case there was a widely diffused inflammatory cellular infiltration of the "rheumatic" type in the heart, conspicuous in the region of the central fibrous body, and the inflammation reached its greatest intensity in the a.-v. node. Cellular inflammatory infiltrations, mostly lymphocytes, were also present surrounding the vessels in the bundle.

In reviewing the cases of heart-block it is necessary to note some negative cases—cases without bundle lesions—that have been recorded. In 1907 Fahr[8] recorded a case in which no lesion was found in the part of the node and bundle examined, but this did not include an examination of the main stem of the bundle at its bifurcation nor of its two principal branches. In 1910 Krumbhaar[9] published a case of block in which there was a diffuse fibrotic change in the ventricular muscle, with atrophy of the neighbouring muscle fibres. There was fibrosis in the s.-a. node, but the a.-v. bundle and its branches appeared to be quite normal with the exception of an occasional increase of connective tissue. In Price and McKenzie's case[10] there was extreme degeneration and cellular infiltration of the cardiac muscle, occurring in foci but not involving the s.-a. node or bundle. The fibres of the a.-v. node had a vacuolated appearance suggestive of fatty degeneration, although they did not think it possible to say. The patient was a child suffering from diphtheria, and the heart-block was associated with auricular fibrillation. In Hume's case[11] the heart-block was also associated with auricular fibrillation, and although no lesion was found in the nodes or bundle the terminations of the branches amongst the ventricular muscle fibres appeared to be degenerated.

The two cases of heart-block which we now report occurred in the course of acute rheumatic carditis in children, and were associated with similar histological changes in the cardiac musculature, but unfortunately in only one was the junctional tissue examined microscopically.

CASE 1.—The patient, aged 16, was admitted to the Sheffield Royal Hospital on August 12th, 1913, under the care of Dr. Arthur J. Hall (to whom our thanks are due for permission to report this case).

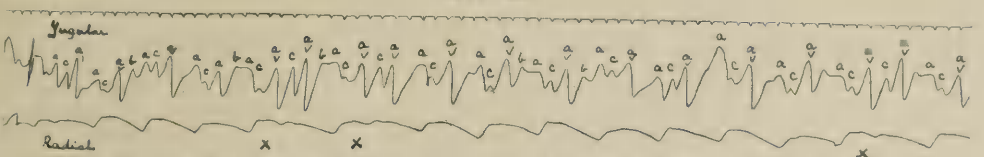
Present illness.—About seven or eight weeks before admission the patient had had what was thought to be an ordinary cold, accompanied by swelling and pain in the right side of the face. For the next two or three weeks she was ailing slightly, the cold coming and going. Five weeks before admission pains had commenced in the limbs and a rash had appeared, consisting of bright red patches covering most of the limbs and trunk. The rash rapidly faded on the following day, but the pains continued, being at first mainly in the legs and subsequently in the arms, and tending to wander from place to place. They varied in intensity from time to time, reaching their maximum about two weeks after the commencement, when they were very severe; during the last two weeks they had largely subsided. Dyspnœa and other symptoms of heart failure had set in and had become progressively worse during the last four weeks before admission, and for the last two weeks there had been some cough and bronchial trouble.

Previous history.—Up to the commencement of this illness the patient had been in good health with the exception of rather frequent colds. She had never suffered from rheumatism, and her heart was thought to be sound. One year previously she had been quite prostrate after an injection of cocaine for a dental extraction, but she was not examined by a medical man on this occasion.

Family history.—The patient's father had suffered from rheumatic fever at the age of 33, but this had not been followed by any heart trouble. Her elder sister had also had severe rheumatism when 16 years old, but had escaped without involvement of the heart.

On admission the patient appeared very pale and ill. There was very considerable dyspnœa and orthopnœa, but only very slight cyanosis. The pulse was irregular, the irregularity appearing to be due to a mixture of a fast rate of about 126 beats per minute and a slow one of about 63. The apex beat was felt in the fifth intercostal space 5 inches to the left of the mid-sternal line. The cardiac dulness extended 2 inches to the right of the mid-sternal line, and on the left was lost in the dulness present at the base of the left lung. A soft blowing murmur was heard at the apex and outwards as far as the middle of the axilla. The sounds over the rest of the heart were faint, and there was but little relative accentuation of the second sound at the pulmonary area. There was no pericardial friction heard. The irregularity of the heart corresponded exactly to that of the pulse. There was some dulness at the bases of both lungs with numerous râles and rhonchi. On the left side these signs were more marked and were accompanied by bronchial breathing. The liver was not felt to be enlarged, and there was no ascites or œdema of the lower limbs. The temperature was 101° F., and the respirations were 48 per minute.

FIG. 1.



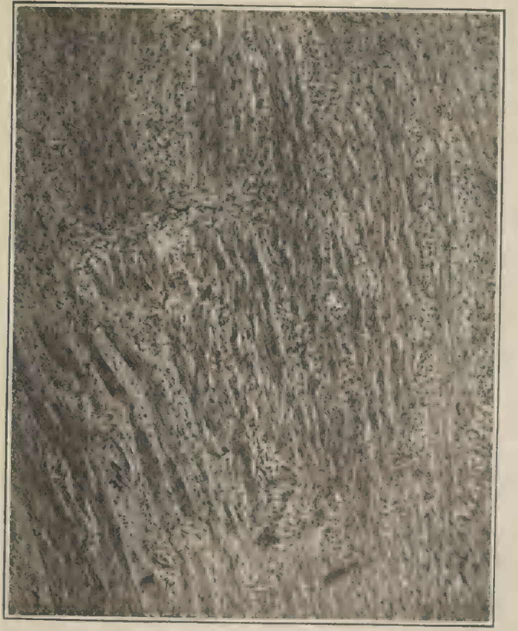
Polygraph tracing from Case 1, showing for the most part 2 : 1 rhythm, with a few beats of 1 : 1 (marked x).

Course of disease.—During the next two weeks the patient gradually became more comfortable, and was able to lie a little lower in the bed. The temperature gradually fell, and between August 18th and 26th did not rise above 99·4°. The respirations became rather less frequent, being more usually below than above 40 per minute. The physical signs in the chest remained almost *in statu quo*, except that the dulness at the base of the right lung diminished. The irregularity of the heart persisted, on some days the quick rate being more in evidence, and on others the slow, but without any definite progression towards a greater or less degree of block. On August 26th the temperature rose to 100°, and for the next three days the patient was not quite so well, the dulness and bronchial breathing at the base of the left lung increasing and the respirations becoming a little more frequent. Towards the evening of August 30th she became much worse, and from then to her death, on Sept. 1st, the dyspnœa was very severe, and she became gradually unconscious. The temperature at this time varied between 101° and normal. The heart irregularity remained as before.

Polygraph tracings.—Although not easy to obtain owing to the severe dyspnœa, these tracings showed clearly enough a condition of partial heart-block, the ventricle sometimes responding to every auricular impulse with a prolonged a.-c. interval, but more usually responding only to every second auricular impulse. (Fig. 1.)

Post-mortem appearances (A. M. K.).—Permission was obtained to make a post-mortem examination of the heart only. There was a diffuse fibrinous pericarditis all over the heart, both visceral and parietal layers of pericardium showing a typical "bread-and-butter" appearance. The two layers of the pericardium also appeared chronically thickened from fibrosis. Over a considerable proportion of the heart's surface the two layers were adherent. There were small endocarditic vegetations along the lines of contact of the mitral valve, and the basal portions of its cusps showed chronic thickening, but there was no gross narrowing of the valvular orifice. Similar vegetations were present on the aortic cusps, and there was some hypertrophy of the right ventricle, but nothing else of note visible to the naked eye. A block of tissue was removed from the cardiac septum, which contained the pars membranacea septi, the adjacent portions of the auricular and ventricular muscular septa, the central fibrous body, and the attachments of the anterior cusp of the mitral valve. The block extended sufficiently far back to include the mouth of the coronary sinus, and it was cut out in such a manner that its long antero-posterior diameter was at right angles to the long axis of the heart. Such a block includes the whole of the a.-v. node and the main stem of the a.-v. bundle, with a portion of its two principal branches. It was cut in serial section from above downwards in the horizontal plane, and a series at intervals of five were mounted and stained with hæmalum and van Gieson's stain. Examination of the sections showed excessive fibrosis spreading from the base of the mitral valve inwards and downwards to the membranous septum, and causing distinct thickening around the a.-v. bundle. In a similar way the central fibrous body was considerably thickened, and the fibrosis extended across to the base of the tricuspid valve, but not on to the valve segments. This fibrosis was infiltrated with inflammatory cells, polymorphonuclear leucocytes and round cells to a marked extent, the infiltration being most intense in its deeper parts and extending upwards into the mitral cusp. In the fibrosis below the tricuspid valve and in the neighbourhood, in addition to the above-named inflammatory cells, there were numerous "giant cells" of the so-called "rheumatic" type. In the a.-v. bundle there was extreme swelling of all the connective tissue between the bundle fibres. The swelling was caused by inflammatory œdema, and the tissue showed well-marked infiltration with inflammatory cells, both polymorphonuclear leucocytes in abundance and round cells. Focal collections of inflammatory cells were also present in the bundle, and its margins were infiltrated with similar cells in great numbers. Similar inflammatory cellular foci were present in the node, and the connective tissue between the nodal fibres exhibited the same kind of œdematous swelling. The fibrous tissue around the arterioles in the node appeared rather excessive in amount and was also swollen. The inflammatory infiltration and swelling of the interstitial tissue were most marked in the main stem of the bundle. (Fig. 2.) In the cardiac

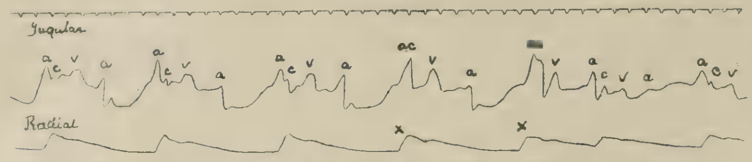
FIG. 2.



From a photomicrograph of main stem of a.-v. bundle, × 90, showing the "bundle" fibres widely separated by the extremely swollen, œdematous interstitial connective tissue, which is abundantly infiltrated with polymorphonuclear leucocytes.

tissue generally many of the arterioles showed periarterial fibrosis, the fibrous tissue being swollen, arranged in whorls, and showing slight infiltration with inflammatory cells. Inflammatory nodules consisting chiefly of round cells and "giant cells" in small areas of swollen interstitial connective tissue were also present, although they were seen but rarely.

FIG. 3.



Polygraph tracing from Case 2, showing 2:1 rhythm, with a single beat of 1:1. The a.-c. interval becomes progressively shorter up to this beat, and it is questionable whether the beats marked x are not ventricular escapes.

Acute inflammatory cellular infiltration was also seen spreading along in the subendocardial tissue, but only becoming marked as it approached the base of the mitral valve.

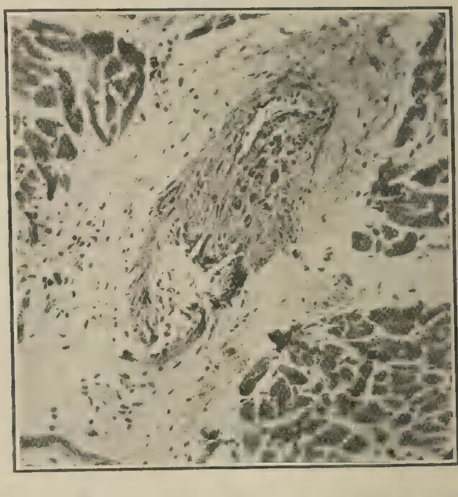
The acute inflammatory condition present in the a.-v. node and bundle in this case, and which seemed sufficient to account for the heart-block, is exactly comparable to the lesions present in the case of heart-block in diphtheria which has been previously published by one of us (A. M. K.[5]). In this latter case acute inflammatory lesions, cellular infiltrations and swelling of the interstitial tissue, involved the a.-v. node and bundle and were associated with a complete block of at least three days' duration. The type of cellular reaction also corresponds to that in Butterfield's case of partial block already quoted.[7]

CASE 2.—This patient first came under the care of one of us (A. E. N.) in September, 1909, when he was 8 years old. The history obtained was to the effect that he had been quite well up to the beginning of that year, with the exception of two attacks of pneumonia some years previously. From April to July, 1909, he had been an in-patient at King's College Hospital, under the care of Professor G. F. Still, with St. Vitus's dance and heart disease. Since then he had been in fair health and had not suffered from shortness of breath. On examination he appeared to be fairly well nourished and of good colour, and there was no dyspnœa after the ordinary exertions of walking and undressing. There was no œdema or ascites. Examination of the heart showed the apex beat in the fifth space, 5 inches from the mid-sternal line. There was a well-marked heave over the apex and also over the præcordium nearer to the sternum. The cardiac dulness extended from 1½ inches to the right to 5¾ inches to the left of the mid-sternal line. On auscultation there was a loud systolic bruit heard at the aortic base and conducted up to the neck; at the third and fourth left interspaces close to the sternum a systolic and a faint whiffing diastolic bruit were heard; at the apex there was a long blowing systolic murmur conducted outwards and round to the back and a short rumbling diastolic. Nothing abnormal was detected in the lungs. The patient attended the hospital on and off at irregular intervals as an out-patient up to the time of his admission to the wards on Dec. 27th, 1912, remaining in fair health with the exception of an occasional cough and one brief attack of mild rheumatism in March, 1910. A few days before admission he had begun to vomit and felt ill.

On admission the patient looked pale and seemed rather ill. There was some ascites and œdema of the lower limbs. The liver was felt 1 inch below the costal margin in the right nipple line. There was some dulness at the bases of both lungs, more marked on the right side, and numerous crepitations were heard. The breathing was not much distressed, but the patient was unable to lie flat; the respirations were 32 per minute and the temperature was 100·2° F. Examination of the heart showed, in addition to what is noted above, some signs of an increase of the hypertrophy and the presence of pericardial friction in the third and fourth interspaces on the left. The heart-rate was 92 per minute, and the rhythm was perfectly regular. For the next two days the pulse remained regular at a rate between 80 and 90 per minute, and then suddenly fell to about 50 per minute and became markedly irregular. Polygraph tracings showed that this irregularity was due to a mixture of 2:1 and 1:1 rhythms complicated occasionally by the presence of premature beats. (Fig. 3.)

Post-mortem examination showed the left pleural cavity to be wholly obliterated by adhesions which could just be broken down, and the right similarly affected except at the base where there was a large pleural effusion of clear fluid. Both lungs were œdematous. There was a considerable quantity of fluid in the peritoneal cavity. The spleen was firm and weighed 4½ oz. The liver weighed 2 lb. 13 oz., and was fibrous and congested. The pericardium was bound externally by recent adhesions; between the two layers there were a little fluid, much fibrin, and a few recent adhesions. The heart weighed 17 oz. The walls of all the cavities were hypertrophied, but more especially that of the left ventricle, measuring on an average about 2½ cm. in thickness. The ring of the mitral valve was thickened, rigid, and somewhat contracted; the valve segments were also thickened and contracted. The aortic valves, too, were markedly thickened. No recent vegetations were apparent. Blocks of tissue from the right and left ventricles and the interventricular septum were cut. They showed more or less wide separation of the muscular fibres by swollen interstitial tissue containing numerous small round cells. Around and near the arterioles there were, especially in the left ventricle, numerous so-called "rheumatic nodules" consisting of round cells and giant cells in swollen interstitial tissue. (Fig. 4.) In places there was marked degeneration of the arteriole wall, which appeared of a structureless homogeneous nature.

FIG. 4.



From a photomicrograph of wall of left ventricle, showing a small artery with a "nodule" in its wall.

We regret that we are unable to give an account of the condition of the a.-v. node and bundle, and to this extent the report is incomplete. No microscopical examination of the junctional tissue was made at the time and the specimen was not kept. We include the case in this paper because the inflammatory changes in the cardiac musculature showed similar characteristics to those in the first case—"rheumatic" type—and it seems possible that similar changes may have been present in the node and bundle, but to what extent we are unable to say.

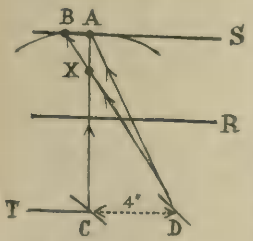
ON THE LOCALISATION OF BULLETS AND SHRAPNEL.

BY WALKER OVEREND, M.A., M.D. OXON.,
HIEF ASSISTANT IN THE X RAY DEPARTMENT AT ST. BARTHOLOMEW'S HOSPITAL, AND HONORARY RADIOLOGIST TO THE EAST SUSSEX HOSPITAL, HASTINGS.

AT the present time, when it is the frequent duty of every radiologist to locate the position of bullets and fragments of shrapnel-casing in the chest, pelvis, in the muscles of the back, shoulders, and other regions, the necessity of reliable and expeditious methods is obvious.

The methods here described depend on the well-known fact of the displacement of the shadow when the target or anticathode is moved out of the direct line. In the figure X is a foreign body situated, for example, in the muscles of the back, the patient lying face downwards. The diaphragm, rectangular by preference, being contracted to a mere slit, the tube is moved until the shadow lies exactly central. The point of a pencil is placed on the centre of the shadow if the object is irregular in shape; if a pointed bullet either on the apex or opposite end. The light is then turned up and the spot is marked on the glass of the screen with a small dot of ink or with a solid ink pencil. The diaphragm is now opened and the target (T) moved to D, 4 inches to the right. The shadow is displaced to the point B; its position is again marked on the screen. As the distance of the target below the edge of the table is known, or may be ascertained once for all, it now only remains to measure the height of the screen (S) above the couch (R), when the distance of the anticathode from the screen or skin is found.



The data we have now obtained are the amount of displacement of the shadow corresponding to a 4-in. movement of the target and the distance of the shadow from the target. To facilitate matters a 4-in. steel rule may be purchased in which the inches are divided into 32 parts. For immediate calculation a table may be consulted consisting of several columns. In the first column the depth of the body in inches is given, in the remainder the displacements of the shadow in 1/32nds of an inch, for 18, 20, up to 30 inches distance of the screen from the anode. The distance between the shadows is measured on the 4-in. scale in 1/32nds of an inch, the column corresponding to the height of the screen is taken with the degree of displacement. This line is followed to the left to the first column and the depth of the object is ascertained.

Before commencing the localisation it is important to see that the tube itself is properly centred. This may be done by placing a circular metallic reel—such as is generally used for surgical plaster—on the couch and the fluorescent screen over it. The position of the tube is now altered in its box until the shadow of the reel corresponds to the reel itself. Before the patient leaves the couch it is necessary to indicate on the skin as a landmark the position of the shadow cast by the direct ray. This may be done by moving a long thin pointed metallic rod beneath the screen until the shadow of the point corresponds with that of the foreign body. Indelible pencil or solid silver nitrate may be used. The whole procedure of localisation need not occupy more than ten minutes.

If the shadow is too small, indefinite, or if very accurate estimation is required two radiograms may be taken on the same plate with the anode in the two positions already described. The measurement is then made between identical points of the shadows in 1/32nds of an inch. The brighter and more definite shadow is that cast by the direct ray. This method may be employed for bullets within the chest, abdomen, large joints, and skull. If the shadow moves with respiration, the *double* radiogram must obviously be taken in the same phase each time.

I have devised a simple localiser which may be employed when the distance between the shadows has been ascertained. It is clamped to the side of the couch directly the two shadows have been marked, and consists of a vertical rod, which carries in a sleeve a horizontal aluminium bar. At the extremity of the bar a *pellet of shot* is fixed. The bar is movable up and down on the vertical rod, also backwards and forwards in its sleeve. Fastened to the rod is an inch-scale and an indicator which at first is situated at zero. Before the patient leaves, the horizontal bar is projected over the screen, and lowered so as to touch it; then it is withdrawn and fixed. This position denotes the height of the screen. After the patient has gone the screen is again placed at the same level and the pellet of shot is brought exactly beneath one of the shadows. The tube and diaphragm are adjusted until the central ray strikes this shadow; the diaphragm is opened, and the tube moved four inches in a direction opposite to the second shadow. The shadow of the shot does not change its position, since it is situated exactly at the screen (see figure). The scale is now fixed, and the shot with the bar slowly depressed. Its shadow moves towards the second; when it is at the same level the bar is clamped and the depth is read on the scale.

In the upper arm, thigh, and calf it is not always easy to find the bullet even after crosses have been made at right angles to each other. The safest plan, perhaps, is to place the limb, with the assistance of the surgeon, in the *exact* position in which the operation will be performed, and localise the depth in the manner mentioned above, either by marking the two shadows on the screen or by taking a *double* radiogram. If the aperture of entry is near the shadow a tiny piece of adhesive lead foil as an additional landmark may be placed over it before the single or double radiogram is taken.

The localiser, calculating tables, and rule may be obtained from Mr. Leslie Miller, 66, Hatton-garden, London, E.C.

St. Leonards-on-Sea.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF RUPTURED UTERUS WITH INTACT MEMBRANES.

By LEWIS GRAHAM, M.S. LOND., F.R.C.S. ENG.,
HONORARY SURGEON, BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN; HONORARY OBSTETRIC REGISTRAR, MATERNITY HOSPITAL, BIRMINGHAM.

THE following rare case will, I think, prove of interest to the readers of THE LANCET.

The patient, aged 34 years and in her fourteenth pregnancy at full term, was admitted to the Birmingham Maternity Hospital at 3 A.M. on August 14th, 1914. Her previous labours had been normal. She had been in an infirmary during the last week of June this year on account of abdominal pain and vomiting, and while there was given an anæsthetic for thorough abdominal examination, but as nothing was found she left.

When admitted to the Maternity Hospital the patient stated that she had "had a flooding which went through the bed." On examination nothing abnormal was found except slight cystitis. The os admitted a finger. The head presented and the fœtus was alive. At 9 A.M. she complained of "stomach ache, not like labour pains." At 12.30 she had the same pain and the os was now the size of a five-shilling piece. At 3.30 she complained of a "click in the right side." She also began to lose more than normal. Her appearance changed and she looked grey and pinched. The pulse was 88. The fœtal heart was not heard. The abdomen looked more square and full; it was quite soft and slightly tender. The membranes had not ruptured and the fœtal head could not be felt. At 5 P.M. I saw the patient. She was having no pains, but her condition was so grave that I ruptured the membranes, seized a foot, and extracted a dead but otherwise normal child with ease. Immediately on delivery the woman's condition, bad before, became much worse. I then examined again and felt a long anterior rupture of the uterus with the placenta lying in front. The latter I withdrew. The woman now appeared to me to be dying. She had no pulse at the wrist and her respirations were only the faintest occasional sighs. I put into the vagina a large plug of iodoform gauze and expected her to expire in a few minutes.

While I was getting ready to return home the house surgeon, Dr. Elsie Impey, begged hard that I should do something more for the woman, and with great courage volunteered to give an anæsthetic. It seemed that the patient would die in any case, but that if we operated we should feel that nothing had been left undone to save her. Without the slightest hope of success, under a little open ether, I performed a subtotal hysterectomy. The uterus was severed below the level of the rent, which extended vertically, in front, from the fundus to about the position of the internal os. The gauze was pushed out through the vagina and another piece introduced from above, vessels were ligated and all stumps peritonealised with a continuous suture. All blood in the abdominal cavity was extracted and saline was left in the abdomen. Throughout the operation, which took about 20 minutes, the best one can say of the patient's condition was that she did not die. When the strain stitches were put into the abdominal wall she appeared to have expired, so no intervening skin stitches were put in, and she was just covered with dressing and a binder. Luckily the patient was not dead, and at 10 P.M. her condition was much improved. She was conscious, and had a pulse of 150. For five days she made perfect progress, and one anticipated recovery. On August 19th she had diarrhœa, which was complicated next day by vomiting. Despite all treatment these continued, and she went downhill and died at 1 A.M. on August 22nd.

At the post-mortem examination the pathologist, Dr. Laurence Ball, could find nothing to account for death. The incision was healing cleanly and there was simply a clean suture line of peritoneum in the pelvis. On microscopic examination of the uterus nothing abnormal was found in any part of the wall examined.

Two things in the case impressed me greatly. 1. The force of the uterine contractions were able to make a long complete rupture of the uterus and yet not able to rupture the membranes, though the os was considerably dilated and the membranes of normal toughness. 2. The patient could stand a hysterectomy in so profound a condition of collapse as to resemble imminent death and yet recover virtually from it.

My best thanks are due to Dr. Elsie Impey for her encouragement and perseverance in the treatment of the case.

Birmingham.

NOTE ON A CASE OF ACETYLENE GAS BURN OF THE CORNEA.

BY H. HAWARD BYWATER, M.D. VICT., F.R.C.S. EDIN., D.CH.O.,
HONORARY ASSISTANT SURGEON, EYE AND EAR INFIRMARY, LIVERPOOL.

As I have seen no record of a similar case, I send the following notes for publication.

A motor-lorry driver consulted me early one morning and stated that on the preceding night he was examining an acetylene generator to see if he had put in sufficient water. In order to see the level of the water he struck a wooden match and held it two inches away from the aperture, his right eye being nearer the aperture than the left. He at once heard a report and saw a blue flame, but thought he had escaped any injury. As the right eye became slightly painful the next morning he came to see me.

On examination the lashes of both lids and the hair over the brows were burnt, especially on the right side. On the right cornea there was a central superficial oval-shaped burn; this was longer horizontally and stained brightly with fluorescin. The left cornea was unaffected. The vision of the right eye was 6/18 and that of the left eye 6/6. Four days afterwards the vision in the right eye was 6/9 (3 letters) and seven days after was 6/6.

Liverpool.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—Professor Warrington Yorke, M.D., of the University of Liverpool, and Dr. B. Blacklock, director of the Runcorn Research Laboratory, have left Liverpool for Sierra Leone upon a medical research expedition organised by the Liverpool School of Tropical Medicine. The principal concern of this expedition will be an investigation of the biting insects associated with tropical diseases in Sierra Leone.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Clinical Cases.—Prolapse of the Spleen.

A MEETING of this section was held on Nov. 13th, Mr. J. **CHARTERS SYMONDS**, the President, being in the chair.

Mr. **ALAN H. TODD** showed a case of Probable Injury of the Crucial Ligaments. The patient, a man, aged 30 years, had injured his knee during a football match when he was aged 15; he did not remember quite what happened, but he had to be carried off the field. Nothing was very obviously wrong with the joint at the time and the school doctor sent him into school next day. After walking on it, however, it became very swollen and painful and he had to remain in bed for ten days. No splint was used. The inflammation subsided. For some years after this the joint felt weak. Sometimes it would become swollen and distended, and then walking would be painful. Occasionally it would "go out," in which case there would be severe pain. Sometimes it would reduce with an audible click. The joint, moreover, sometimes became locked, but he had never discovered a loose body in it. He had always been able to reduce the knee by slow forced extension, but had noticed that if he wore an elastic knee-cap this prevented him from "getting the joint back" unless he first removed the cap. At one time, soon after he left school, he used to get attacks of synovitis every few weeks, but lately these had been much less frequent. In the intervals between the attacks he had been able to lead an active, athletic life, playing a good game of golf or tennis daily, though he had always had to avoid turning round too suddenly. Eleven years ago, when out shooting, he jumped on some muddy ground and twisted the knee badly. It was very painful, and a medical man put it in plaster, fully extended, for three weeks. After this he wore a patella-clamp for a while, but as it failed to prevent the joint "going out" he discarded it. A slight genu varum slowly developed after the original accident, but lately it had obviously increased in amount. The patient walked with a slight limp, but there was no obvious laxity of the joint: apparently he had unconsciously acquired the habit of keeping the thigh muscles well braced up when walking. When sitting he could make the leg slide forwards on the femoral condyles at will. There were slight limitation of extension and flexion and some lateral mobility of the joint. Although there was no evidence of free fluid within the joint, or of hypertrophy of the subsynovial tissue, the circumference of the right knee was $\frac{3}{4}$ in. greater than that of the left. This seemed to be mainly due to several large osteophytes which had formed around the internal tuberosity of the tibia and the internal condyle of the femur at their margins. They were well seen in skiagrams.

Dr. **W. ESSEX WYNTER** and Sir **JOHN BLAND-SUTTON** showed a case of Acholuric Jaundice in which splenectomy had been performed. The patient, a young man, had suffered from jaundice and anæmia all his life, with exacerbations at frequent intervals. His mother, maternal grandfather, an aunt and an uncle on the mother's side were similarly affected. The yellowness of the skin apparently increased during the day, being more marked in the evening than in the morning. He had been worse during the past two years, losing strength and $2\frac{1}{2}$ st. in weight. Physical examination disclosed no abnormality of the thoracic or abdominal viscera, except slight increase in the dulness over the spleen, which could just be felt on deep inspiration. The urine was clear, of a deep red-brown, and had a specific gravity of 1025. There were no abnormal constituents, and both Gerhardt's and the zinc chloride tests for pathological urobilin were negative. Hæmolysis occurred in 0·45 per cent. saline solution, which was about normal. The white cells (5200) consisted of lymphocytes, 39·4 per cent.; polymorphonuclears, 57·5 per cent.; and eosinophiles, 2·5 per cent. The temperature was 99° to 100° F. before operation. The spleen was removed in July, 1914, several ligatures being applied close to the hilum, but the main artery was left unmolested. There were no complications, and the temperature subsequently became normal in the course of ten days. Wassermann's reaction was reported positive before operation and negative after. The reaction was considered doubtful 14 weeks later. The patient left hospital after about a month. The red cells were then 1,880,000 and the white cells 13,000. The resistance of the red cells was greater than normal. A white cell count 11 days after the operation showed lymphocytes, 24 per cent.; hyaline cells, 2 per cent.; polymorphonuclears, 73 per cent.; and eosinophiles, 1 per cent. After about four months the patient had put on $1\frac{1}{2}$ st. and had gained strength and been free from attacks of jaundice. Blood count: Hæmoglobin, 80 per cent.; red corpuscles, 3,700,000 per cubic millimetre; leucocytes, 18,000 per cubic millimetre; neutrophile polymorphonuclears, 51 per cent.; lymphocytes, 33 per cent.; transitional and hyaline cells, 11 per cent.; eosinophile polymorphonuclears, 4 per cent.; mast cells, 1 per cent. A few normoblasts were present, and a considerable number of red corpuscles showed nuclear fragments (Howell-Jolly bodies). Resistance of red corpuscles to hypotonic NaCl solution: a faint trace of lysis, 0·45 per cent. NaCl; marked lysis, 0·3 per cent. NaCl. Two presumably normal bloods tested at the same time showed a trace of lysis with 0·45 per cent. NaCl and almost complete lysis with 0·4 per cent.; thus the patient's red cells were of more than average resistance. The Wassermann reaction was suspicious, but could not be called positive.

Dr. **ESSEX WYNTER** and Sir **JOHN BLAND-SUTTON** also showed a case of Splenic Anæmia after Splenectomy. The patient, a boy aged 13 years, had been ailing for six weeks suffering from lassitude and some enlarged glands. He was sent for treatment by the school doctor, and was thought at first to have Hodgkin's disease, but improved under treatment as an out-patient. On admission in July, 1914, the boy was seen to be anæmic and thin, but made no definite complaint of pain or discomfort. The thoracic and abdominal viscera appeared normal apart from the spleen, which was much enlarged and extended $4\frac{1}{2}$ inches below the left costal margin and inwards to the middle line. Small, firm glands could be detected in the neck, axillæ, and groins. The thyroid was enlarged, especially the isthmus. Blood count: Red cells, 4,200,000; white cells, 2600; hæmoglobin, 60 per cent. A differential count showed no disturbance of the ordinary proportion in white cells. Temperature 99° F. Urine normal. Splenectomy was performed in July. There were firm adhesions, separation of which involved considerable bleeding and some injury to the diaphragm. A gauze drain was inserted, but the wound healed readily, and stitches were removed on the eleventh day. The spleen was large and firm. For ten days after operation the temperature rose to 102° and 103°, and thereafter gradually subsided. Movement of the diaphragm was arrested, especially on the left side, and there was collapse of the lower lobes of the lungs with bronchitis. This gradually cleared and the patient was convalescent after five weeks. Then the blood count was as follows: Red cells, 3,650,000; white, 21,000; polymorphonuclears, 48·5 per cent; lymphocytes, 21 per cent.; eosinophiles, 5 per cent.; and transitional, 25·5 per cent. In November another blood count showed: Red cells, 4,800,000; white cells, 8000; hæmoglobin, 62 per cent.

Dr. **G. HELY-HUTCHINSON ALMOND** showed a case of Myositis Ossificans (juvenile progressive type). The patient, a girl, aged 7 years, was healthy as a baby. Fifteen months ago, when aged $5\frac{1}{2}$, her right hip began to get stiff, and was followed by the left; the stiffness was intermittent at first, but they had gradually become more fixed. She could only walk about 100 yards, and tilted her pelvis up on both sides with each step. She was thin and her muscles were badly developed. There was a slight list of the spine to the left with corresponding curves and raising of the right shoulder. A small patch of ossification could be felt close to the insertion of the biceps of the left arm, and a patch of hardness near the origin of the biceps of the right. The ilio-tibial band on the left side was ossified from its origin to its insertion. The hamstrings of the left thigh were ossified, a skiagram giving the appearance of a calcified shell enclosing the muscles. There was a lozenge-shaped patch of hardness in the outer belly of the left gastrocnemius. No definite patches of hardness or ossification could be made out in the muscles of the spine or trunk.

Mr. **W. J. MIDELTON** showed a case of Dermatitis Herpetiformis with Tuberculous Glands in the Neck. The patient was a girl aged 9 years. She had been well up to the age of 3, but then developed scarlet fever. An eruption occurred after the original rash had died away and was diagnosed as dermatitis herpetiformis. The dermatitis continued. She had been free from the dermatitis from the beginning of August to the end of September, 1911; then it recurred and persisted. Counter-irritation had been commenced at the end of February, 1912. At that time the pustules, blebs, and scabs were well marked, chiefly on the inner aspect of the upper third of the thighs and spreading on to the abdomen. Within three weeks she became well. Occasional slight relapses of short duration had occurred since. About five years ago some tuberculous glands in the neck were operated on and sinuses persisted for over two years. These eventually healed well, but one scar remained bluish-red and had whitish specks in it suggesting lupus vulgaris. In May, 1913, she had a wound on the right wrist which became septic, but soon healed under treatment. In August, 1913, one or two glands in the neck enlarged and one small abscess formed. This was incised, and complete healing took place in a few months. Other glands became inflamed, but no definite abscess occurred. This fact was, in his opinion, significant as showing greatly increased resistance. No sign of the dermatitis had appeared for over 18 months.

Mr. **Midelton** also showed a case of Dermatitis Herpetiformis and Chronic Bronchial Catarrh in a boy aged 9 years. He had been treated by means of continuous counter-irritation commenced in August, 1912, and carried out once a week ever since. The treatment seemed to check the eruption and the boy's general health had much improved.

Mr. **Midelton** also showed a case of Severe Neuritis following Sepsis in a man aged 42 years. He also had been treated by continuous counter-irritation by multiple puncture and irritants. Applications had been made once a week on various parts of the trunk and arms. Recovery had followed.

Mr. **Midelton** also showed a case of Polyarthritis and Severe Neuritis in a man aged 48 years. One year ago pains occurred in arms and headaches returned; pains also in legs, at times severe, lately very severe indeed. Joints of fingers swelled, also knee-joints to some extent. Some slight muscular wasting, especially interossei. At times almost helpless. No drugs were of use in relieving the pain. Knee-jerks absent. Treated with benefit by means of blisters and savin ointment. A blister, 4 in. by 4 in., was applied over the upper dorsal vertebræ and left on 12 hours. This was then removed and a raw surface left. Savin ointment was then applied on lint over the raw place and left on for 12 hours. By repeating this dressing regularly every 12 hours a free, purulent discharge was maintained for 12 days. Zinc ointment was then applied and the raw surface healed rapidly and soundly within three days.

Dr. H. **Batty Shaw** showed a case of Hemihypertrophy in an otherwise healthy girl aged 11 months.

Mr. W. G. **Spencer** read a short paper on a case of Retroperitoneal Prolapse of the Spleen into the Left Loin.

MEDICAL SOCIETY OF LONDON.

Continued Discussion on Surgical Experiences of the Present War.[1]

A meeting of this society was held on Nov. 23rd, Sir **John Bland-Sutton**, the President, being in the chair.

Mr. **D'Arcy Power** said that the wounds which had come under his care were the result either of the conical bullet, of the round bullet, of pieces of shrapnel cases, or of the explosion of large shells. He had seen no case of injury due to bayonet, lance, or sword. He instanced two cases as showing the force of impact. An officer was wounded by a large shell which burst within ten yards. The skiagram showed the presence of foreign bodies deep in the erector spinæ. Subsequent examination proved that two of these substances were sovereigns which had been driven out of a money belt he was wearing straight down on to the transverse process of the first lumbar vertebra, which was smashed to pieces. The coins themselves were twisted and concave; one had upon it the impression of the milled edge and part of the obverse of that which lay above it. In the other case part of the patient's diary had been driven into his thigh and for many days afterwards he shed pieces of its leaves. The most interesting, as well as the most difficult cases, were those in which there had been injuries to the nerves and the nervous system. It was necessary to decide whether the subsequent disturbance was due to damage done by the bullet in its passage or whether it was caused by the bullet as it lay *in situ*. In many cases this could only be determined by the careful examination of a skilled neurologist acting in association with a first-rate X-ray photographer. In such cases the surgeon's action must be governed by their reports. If the damage was done by the bullet in transit its removal would be of no benefit, whilst if the projectile itself was causing irritation it must be removed. He held, therefore, that each case must be considered on its merits, and that it was unnecessary for surgeons to remove every bullet or piece of shell merely because it showed up clearly on a skiagram. The most interesting injuries to the nervous system and nerves were those to which the non-committal name of "concussion" must be given for the present. They had to be distinguished from laceration, hæmorrhage, compression, and other tangible conditions by the fact that no gross lesion was presented by examination during life. They occurred in the peripheral nerves as well as in the spinal cord. Experience showed that the X-ray photographs as they were usually presented were not infallible guides either to the position or to the depth of a foreign body. It might be necessary to undertake an extensive exploration before a bullet was discovered, or it might even be missed altogether. Sloughing rather than suppuration was a feature in most of the wounds, and it was interesting to observe that in many instances where a bullet had passed completely through a limb it was only the inlet and outlet which remained as wounds, the intermediate track having healed. The cause of infection seems to have acted after the injury and not at the time. In consequence of the sloughing secondary hæmorrhage needing ligature of the main artery in its continuity was tolerably frequent. When wounds which had healed became painful it was necessary to reopen them, and in every case the pain seemed to have been due to pieces of clothing which had been left in the tissues, at first without causing irritation. Dry dressings in most cases had had to be replaced by fomentations. Iodine had been employed extensively in the form of 1 drachm of a 2½ per cent. solution in a pint of warm water applied on absorbent cotton-wool. The iodine volatilised if the water was too hot; it was converted into an inert iodate if a starch-containing dressing was used. Much time could be saved if the gaping edges of flesh wounds were brought together by a gridiron of strapping; union by third intention, which was healing by the union of granulations, then took place just as it did in a baby whose hare-lip had failed to unite at once. Mr. Power concluded his remarks by pointing out that the surgeon needed constant help from the physician, the neurologist, the pathologist, and the radiographer if he was to obtain the best results for his patient, that he must know when to stay his hand and when to operate, and that his attitude should be rather from than towards operation. It was better to lay wounds freely open than to plug or drain them.

Mr. J. **Charters Symonds** said that before speaking on the general question he wished to express his entire agreement with the broad principles laid down by Sir Watson Cheyne.[2] He (Sir W. Cheyne) had brought them back to the time when septic infection was the rule, and had shown that the same conditions still prevailed when wounds were exposed and must be met by the methods originally introduced by Lister. Those who worked in hospitals in the early "seventies" must recall with him many old experiences now recurring and agree with Sir W. Cheyne's condemnation of the gauze drain when suppuration existed, of the imperfection of much of the so-called sterilisation, and of the tendency of an operator to attribute failure to any cause but that due to his own lack of watchfulness. The address he had given was a fine confession of faith, and he (Mr. Symonds) would cordially endorse his advice to younger men to read the account of Lister's early work, accessible in those admirable volumes, in the preparation of which his two old pupils and assistants, Cheyne and Godlee, took so large a part. It was with some hesitation that he accepted the invitation to speak on this subject because of his limited experience. Yet he supposed it to be in character not unlike that of most others who had been in charge of hospitals at home.

---

[1] The Lancet, Nov. 21st, 1914, p. 1200.

[2] The Lancet, Nov. 21st, 1914, p. 1185.

Though it was not the time to formulate definite lines of treatment, much good might result by an interchange of experience, for they did not all of them treat these injuries in the same way. He proposed to confine his remarks to the question of septic wounds near the large vessels, to the management of septic comminuted fractures, and of wounds of joints already septic, for here life and limb were in peril and the surgeon's whole purpose should be concentrated upon the saving of both, leaving refinements to a later period. The wounds of large vessels—of which two interesting examples had come under his care—and of nerves, of which there were also many, and of the lung and pleura must be omitted. The head injuries he hoped someone else would deal with. A point that must have struck everyone was the septic condition of all but the simple direct bullet wound. The cases had come under care from two to ten days after the infliction of the wound, which even in 48 hours had been septic and the later ones so offensive as to be unbearable, yet the remarkable thing about these cases was the absence of toxæmia. The temperature, even in the fractures, was normal, and the pain where one of two parallel bones was broken trivial. This septic condition must be attributed to the length of time the wounded had lain out in the open, often two and three days before help could reach them, and to the urgency of clearing the field hospitals. There had been no time for full disinfection such as Sir W. Cheyne rightly desired to see, and which was hoped would now be possible, owing to the shifting of the base and the better provision of hospital accommodation. Though most of the wounds on arrival were septic, this was not from the lack of careful dressing *en route*. The Belgian contingent, for instance, had all been dressed on the ship or on the train, and he would like to pay a tribute to the admirable attention these and the other cases received in transit, involving as it must have done a great amount of work on the part of the medical officer in charge and chief of the Red Cross nurses. Why was toxæmia absent in most of these cases? Did the missile sear the tissues in its passage? Certain it was that constitutional effects differed widely from those seen in wounds of equal septicity in civil life. In the treatment of the ordinary flesh wounds he had rested content with frequent boric acid fomentations—not even employing irrigation. In some a 10 per cent. solution of argyrol had been of service. With regard to comminuted fractures by bullets or shells, he believed the best plan, again, was to be content with warm antiseptic applications. To take the first case he was called upon to handle, a drummer in the Loyal North Lancashire with a smashed humerus. The man came in on the sixth day, in great pain, foul pus escaping from the openings, the skin inflamed and sodden, and yet the temperature was not raised. He looked ill and wasted, chiefly from exhaustion, for he had undergone the terrible hardship of the long journey to St. Nazaire. A small dependent opening was made for the better drainage, and a rubber tube passed through. In doing this it was ascertained that the bone was broken into many fragments. Careful dressing once a day with gauze and wool and firm splinting led to rapid improvement. At the end of three weeks the bone had united. He left after four weeks with one sinus and a strong arm. Another man had a bullet through the tibia, splitting off a large fragment from the front, and though a direct wound this was septic and most offensive. Rapid union ensued here also under boric fomentations without any irrigation. There remained a sinus leading to bare bone which must be dealt with later. It was somewhat tempting to open up and disinfect the humerus and remove some of the fragments, and again to plate or wire the tibia. The results exemplified the truth of Sir Watson Cheyne's conclusions that it was far better to leave cases alone; strong limbs would result, though there might be a little imperfection in alignment. He had found bullet and shell wounds of the tarsus more septic and more difficult of recovery. Was this because the joints were involved, or because of the softer character of the bones? Was it wise to depart from the method of non-interference and to curette these cases, say, in the third week? He had just carried out such treatment in a tarso-metatarsal injury and in a carpus. The immediate result in the latter was an increase in the pyrexia from 101° to 104°. In neither was the result sufficiently advanced for drawing any conclusion. While it was, he thought, generally agreed that the better method of treating these wounds was to be content as a routine practice with the application of boric fomentations and gently washing with peroxide of hydrogen or some mild antiseptic, there were some instances where the question must arise as to whether more active measures should not be undertaken. To take two examples—one where a main vessel lies in the wall and another where a joint is involved. Some of the septic wounds of the thigh had caused him no little anxiety for some days. A bullet entered the outer and back part of the thigh, passed forward behind the femur, and took its exit an inch inside the line of the superficial femoral. There being great pain and no improvement in the septic condition, the wound was examined under an anæsthetic, the greatest care being taken to avoid injury to the surface. The femoral sheath must have been exposed, for the vessels stood out from the inner surface of the track as a rounded cord. Beyond avoiding all injury and rough irrigation the case was left and had done well. So great was the danger of secondary hæmorrhage that he deemed it necessary to have a tourniquet by the bedside and the attendant instructed in its use. In another a ricochet bullet carrying a sharp hook-like projection from its base tore across the line of the femoral just above the apex of Scarpa's triangle. The track, some six inches in length, discharged offensive pus. Though it was impossible to clean this wound, then some four or five days old, the recovery under boric acid fomentations took the usual time of two or three weeks. These gave rise to some anxiety, and he would raise the question whether such wounds should not be enlarged to afford better means for disinfection. One thing which seemed to him to be necessary in such cases was to remove any fragment of shell, bullet, or clothing with as little disturbance of the parts as possible, and to provide efficient drainage by means of a large rubber tube. This might involve an incision in a dependent part. The liability to secondary hæmorrhage would be increased if the patients had other injuries and were also septic. If seen within a few hours of the injury and the wall of the vessel was exposed, should the artery be ligatured when the wound was being cleaned, or should this be deferred in the expectation that if the disinfection had been effective the danger of secondary hæmorrhage had been reduced to a minimum? The wound becoming septic, should the main vessel be ligatured and divided in the wound, or was it better to combine this with proximal ligature? Or, again, was proximal ligature sufficient? To take a case in point: an officer arrived ten days after being severely wounded in three places. The left arm had been amputated in the field hospital and showed limited suppuration. The right foot was swollen and septic from a bullet wound of the tarsus, the ankle-joint, as was discovered in a few days, being involved. There was a ragged septic wound on the inner side of the knee leading deeply into the popliteal space, and the skin of the leg was also red and infected. From the popliteal wound issued most offensive pus. The man was wasted, grey, and septic, the temperature 103°, and he suffered a good deal of pain, borne with that admirable courage which all must have admired in those who had come home seriously injured. He would not enter into such great detail if a large principle were not involved and were not this an example of a considerable class, though it must be admitted that each case must in the end be treated on its own merits. Should immediate amputation have been performed through the thigh in this case? Should the popliteal space have been opened up and the condition of the parts ascertained? He improved in a general way for three days, the temperature fell and the popliteal wound became cleaner. Then fresh infection arose and the temperature reached 103° on the seventh day after admission, the seventeenth from the injury. On this day the ankle-joint was opened and pus evacuated. Ten days after admission and 21 after the injury slight hæmorrhage occurred from the popliteal wound. This being repeated next day, he opened the wound and on passing the finger gently in there came a great burst of bleeding, and it was obvious that the main vessel had been opened. A small fragment of the nickel casing of a bullet was found lying outside the vessels. The artery was with some difficulty secured above and below the wound and then it became obvious that the vein also required ligature. As he proposed, notwithstanding the slender chance of recovery, and in view of the septic condition of the leg and foot, to avoid amputation if possible, a kangaroo tendon ligature was placed on the femoral at the apex of

Scarpa's triangle as a further protection. Next day, the foot being discoloured and the leg cold, amputation was performed through the thigh. Though the condition was unfavourable in all respects, he was glad to say the patient was recovering. An examination of the popliteal space when the man was first seen would doubtless have revealed the injury to the vessel, seeing it was then 10 days old. This would in all probability have precipitated amputation, with the man less able to bear it than he was after a week's rest. Dealing alone with these wounds in a septic condition, he was disposed to think the better practice was to examine and drain, and if the artery was found to be exposed and its sheath injured to ligature the main trunk some distance above—e.g., the brachial in the case of the forearm or the femoral for popliteal injury. He did not mean to say that local ligature of the smaller vessels was not in many cases sufficient. Recently he had to lay open the calf for smart secondary hæmorrhage coming from what he took to be the peroneal artery. The bleeding point was ligatured and the wound treated successfully by the open method. There must be many such cases, and whilst amputation offered an easy and, other things being equal, a comparatively safe way out of the difficulty, it would seem reasonable, in view of improved methods, to go much further in the attempt to save a limb than formerly was justifiable. There was one other subject to which he wished to refer, more to ask for than to give information. What was the best method of immobilising and transporting cases of fracture of the femur? Of all injuries these must suffer most in transit. It might be impossible to keep them in an advanced base, and he was told that when the base was at St. Nazaire the order was that all cases should be sent home. When the wound was being cleaned, was it wise to apply a plate with a view to fixation during transit? Where the wound was large and the bone exposed, and an attempt was being made to save the limb, it seemed to him, judging from his experience of compound fractures, to be a sound practice to apply a plate. In the case of the tibia and fibula his practice at Guy's Hospital was to plate in compound fractures when it was otherwise difficult to secure good position. In bad cases the plate had to come out and was sometimes exposed throughout the whole period of its employment. It served to retain the fragments in position, while the muscles wasted and the surrounding callus formed and enabled more satisfactory dressings to be applied. In itself the plate might have done some harm, but the final result was, in the severe cases with loss of skin, better in his judgment than could have been otherwise secured. So that he would, did the opportunity occur, employ plating or wiring, preferably the former, in suitable cases. To open up any clean bullet wound except to secure a large vessel was a practice which could not be defended even by the most ardent advocate of plating fractures. For transit, so far as he was able to judge, Hodgen's wire splint, designed by this surgeon during the American Civil War for the very purpose, was still the best. The frame should be suspended as Hodgen directed from a hook at the end of the ambulance. In this connexion he fully agreed with Sir Frederic Eve that no other splint permitted the dressing of compound fractures more conveniently and with less distress to the patient. It seemed to him to possess no rival. Having stated his own suggestions, gleaned from civil experience, and thus raised a very important question, he hoped there might be someone present with first-hand knowledge who would be able to say how these severe cases were being handled. In discussing the value of antiseptics Sir Watson Cheyne had done good service in bringing them back to the merits of carbolic acid. It was good to hear that Lister's greatest exponent had not lost faith in an antiseptic with which the earliest and greatest triumphs were secured. While he had himself relied upon carbolic and mercury in the immediate treatment of compound fractures and suppurating joints, he was bound to admit that the 2 per cent. solution of iodine in rectified spirit had given remarkable results in the treatment of large lacerated wounds with or without involvement of bones. It would be an interesting inquiry—which he hoped someone would institute—to ascertain the separate value of each component of this preparation. He was inclined to think that the alcohol would be found to take no small part in the beneficial results. In some form probably alcohol had been used in the treatment of wounds from time immemorial, as in the rite of circumcision. He fancied there was more than met the eye in the application of wine and oil applied by the Good Samaritan, who might with much good reason be considered the first antiseptic surgeon on record.

Dr. W. IRONSIDE BRUCE exhibited a large number of radiograms showing the effects of gunshot injuries. He said that X rays could determine the exact position of a bullet in the tissues, and if the skin was marked it ought, theoretically, to be possible to cut down directly upon it and remove it. There were certain difficulties, however, which were encountered: 1. The distance, as estimated by X rays, conveyed nothing anatomically as to the situation of the bullet, for this depended upon the thickness of the skin, the subcutaneous tissues, &c. 2. For localisation it was necessary to make use of a vertical plane, and this should be followed absolutely at the time of operation. When, owing to surgical requirements, this was deviated from, no further use could be made of the X-ray localisation. 3. Immediately the incision had been made the marks on the skin were no longer useful. Consequently, the accurate information obtainable by X rays could not be utilised to the full.

Mr. W. H. H. JESSOP said that X rays gave certain evidence of foreign bodies in the eye. He had been impressed by the extraordinary number of cases of patients brought over from the war who were blind. He had seen four such. Nothing was observable by the ophthalmoscope, and without treatment other than rest perfect sight had been regained. In two others the blindness was accompanied by blepharospasm. These had also completely recovered. All had been exposed to shell fire, and, he thought, had probably been affected by it. He cited also the case of a patient who had formerly had miner's nystagmus. The man had enlisted, and after driving horses the nystagmus had returned.

Mr. R. P. ROWLANDS said that Sir Watson Cheyne in his valuable address had wisely confined his attention to the most vital question of all. The rapid and smooth healing of wounds was of the greatest importance to the soldier and to the country. Suppuration placed his life in jeopardy and militated against his early and complete recovery. It greatly interfered with primary or early operation for the repair of injuries of special structures, such as nerves, tendons, or bones. It was well known that secondary or late operations for these injuries were more difficult and less successful. When many men were seen returning with septic wounds, the dirty conditions under which most of the injuries were sustained should not be forgotten, and especially the unavoidable delay in treatment. It was very difficult for them, working under the most favourable circumstances at home, to realise the awful conditions of the war and the unparalleled difficulties which confronted their *confrères* in France, who by common consent were doing such devoted and heroic work. It was their duty to offer fair criticism and to help by suggesting practical methods which might be expected to improve the results. They could do this by (1) laying stress on the Listerian principles which governed the successful treatment of soiled wounds, and (2) by making some definite practical suggestions which could be actually carried out under the difficult and unexpected circumstances of this war. Sir Watson Cheyne and others had dealt with these points with great ability and detail. He would confine himself to some more general remarks. Most of the shell and shrapnel wounds were of necessity laden with bacteria from the skin, clothes, or from the peculiarly infective soil of Northern France or Belgium. The risk of infection from each of these sources was far greater than it was in the Russo-Japanese war. There, frequent bathing and changing into clean clothes, the absence of infective soil, and the intense cold were all favourable circumstances, which probably accounted for the good results obtained. It was obvious that clean and dirty wounds required very different treatment. Most were fairly satisfied with the aseptic treatment of clean operation wounds. The less these were irritated by mechanical or chemical violence the better they did and the greater freedom there was from pain. Before the revelations of this war most of the medical men at the front were so very familiar with the brilliant results of aseptic surgery and had so little experience of soiled wounds that the introduction of strong antiseptics into the wounds was abhorrent to them. They feared pain and sloughing. But dirty wounds required cleansing as soon as possible before bacteria multiplied and invaded the tissues. This was best carried out by a combination of mechanical and chemical means. The longer the interval since the accident the more necessary were strong antiseptics which were capable of permeating the invaded tissues and inhibiting the growth of bacteria. Unfortunately strong antiseptics were useless and even harmful after 24 or 36 hours, and a great many of the wounds could not be adequately treated within that period. Under the present circumstances the antiseptic used must be strong enough to destroy spores in a short time. Strong antiseptics might prove to be particularly valuable when thorough mechanical cleansing could not be carried out owing to delay in getting to the field or base hospital. Liquefied carbolic acid was certainly a very powerful and valuable antiseptic which he had often used with advantage for earth-soiled wounds. But if we recommended its routine use difficulties of supply and cost might soon arise. Therefore he suggested the appointment of a committee of surgeons, bacteriologists, and chemists to discuss the variety and strength of suitable antiseptics. Their report would probably be very valuable. For sterilising the skin his colleague, Mr. Turner, had found picric acid, 1 per cent. solution in methylated spirit, at least as efficient and very much cheaper than the solution of iodine in general use. The most suitable dressing should also be discussed, for secondary infection of the apertures of bullet wounds seemed to be occurring in some cases. As regards other details of the primary treatment, free drainage and adequate antiseptic dressing were most important. When wounds were already septic free drainage, irrigation baths, and fomentations were the chief indications. Radical operations for the repair of nerves, tendons, and bones had to be deferred until sepsis had subsided. In conclusion, he said that it seemed to him that hope of improvement depended upon: 1. Getting the patients into the field or base hospitals earlier, especially by the use of special motor field ambulances instead of the slow and uncomfortable horse ambulances. 2. Increasing the staff and general facilities for cleansing the wounds at the field and base hospitals. There were numbers of medical men anxious to serve in this way. The present facilities made it quite impossible to carry out the routine treatment advised by Sir W. Cheyne. 3. More facilities for bathing and changing garments for the men in the fighting line. 4. Moving bad cases as little as possible. Now that the base was fixed it ought to be possible to keep the bad cases still and under observation. It was difficult or impossible to treat these cases adequately during long journeys to England. They all knew that the difficulties of the organisation and adaptation of the Royal Army Medical Corps in this war had been enormous, and that in spite of shifting bases and unforeseen circumstances the service had been brought to a state of efficiency unequalled by that of any other army. Still much remained to be done for the greater comfort and better treatment of the wounded. This great and rich country ought to provide everything for the sick and wounded without the aid of any outside society. Everything ought to be under one supreme head, and that head a medical man, who should have perfect freedom of action. He should be free to order as many medical men as were required for the front from time to time.

Mr. R. H. **JOCELYN SWAN** said that he had had experience of about 2000 cases of men wounded from the front at the Herbert Hospital, Woolwich. He thought the chief features in the treatment of septic cases were adequate drainage and disinfection. Nearly every case was septic, and the point of greatest importance was what was the best treatment to be applied at the front. They could not but realise the great difficulties experienced by the Royal Army Medical Corps, who were often working under fire, not only in the fighting line, but also in the field hospitals. At Woolwich, dealing with wounds which were already septic, they had opened them freely, washed out with hydrogen peroxide or weak permanganate solution, and drained without attempting to sew them up until the sepsis had been controlled. The organisms they had most commonly found were staphylococci, streptococci, these two combined, and organisms of the proteus group. There had been ten cases of tetanus. These had been treated by opening up the wound, disinfecting it with hydrogen peroxide, and injecting by lumbar puncture large doses of antitetanic serum. Two had died, seven were well, and one was still under treatment. He thought it wiser not to attempt an amputation when symptoms of tetanus had commenced, but to be content with opening up the wound freely. There were three cases of malignant œdema,[3] and pyocyaneus infection was not uncommon. A considerable number of cases of secondary hæmorrhage had occurred. Like Mr. Symonds he had been impressed by the lack of toxic symptoms, even in cases so severe as when large collections of pus formed in the knee-joint. There were 18 examples of skull injuries where the bullet entered and passed into the brain. In five the brain had been traversed completely, and two of these got quite well after the depressed fracture had been attended to. There were several cases in which the scalp wound was very small, but much comminution of the skull had taken place perhaps associated with cerebral abscess or subdural hæmorrhage. He thought that skull injuries should be dealt with forthwith, but abdominal and thoracic injuries were often well left alone. Cases of injuries to the chest with fluid in the pleura other than pus did not require surgical treatment. The same was true of abdominal injuries even if it appeared that the intestine had been traversed. He was averse to looking for bullets because X rays had shown their presence except in the case of skull injuries.

Sir **JOHN BLAND-SUTTON** said he had followed Sir W. Cheyne's opening remarks with the keenest interest. No advance, however, could be made by simply following in the paths of predecessors. Lord Lister himself had perpetually introduced changes in his methods. The middle course was the path of safety. While taking advantage of aseptic procedures, it was impossible altogether to avoid antiseptics. He himself had given up carbolic acid because he was peculiarly susceptible to its effects. For many years he had used perchloride, but lately had taken to iodine and was pleased with its results. It was a striking thing that, although these wounds were septic, they cleared up rapidly with fomentations and particularly well with peroxide of hydrogen, and when the sepsis had subsided foreign bodies could be cleared away, the wounds healing with astonishing rapidity.

The **PRESIDENT** announced that the next meeting of the society would be devoted to a discussion on the Treatment of Tetanus.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Enteric Fever in War.

A **MEETING** of this society was held on Nov. 20th, Sir **HAVELOCK CHARLES**, the President, being in the chair.

Sir **WILLIAM OSLER** read a paper on the subject of Enteric Fever in War. He stated that the Empire was confronted with a great task in which the medical profession might take a leading part. Camp diseases had always played an important part in war, but of these enteric fever was by far the most serious, and, so far as this was concerned, we were now being put on our trial. There were four chief points to be noted: (1) The importance of the individual as a factor in infection which demanded careful preventive measures, and in particular the sterilising of the fæces and urine; (2) the existence of mild and unrecognised cases which were difficult to diagnose and which were often mistaken for malaria or pneumonia, as had happened in the Spanish-American and South African wars; (3) the discovery of typhoid carriers, who are a source of great danger, especially where they may be concerned with the handling of food, as in the case of cooks, bakers, or milkmen; and (4) the possibility of protection by immunisation which had produced most striking results. These were particularly shown in the case of antityphoid inoculation in the United States Army, which was voluntary from 1909 to 1911 and compulsory since 1911. The figures which he quoted were well known, and they were in his opinion conclusive as to the benefit of this measure of prophylaxis. Referring to the possibility of unpleasant after-effects, he had taken the trouble to investigate any cases which had been brought to his notice. Usually there were only some slight headache and rise of temperature on the day succeeding the inoculation, with some diarrhœa or constipation. There was, however, the possibility of more serious symptoms developing. As regards England's present position, he regarded this as singularly favourable, though it had to be remembered that there were 1600 cases of enteric fever in England in 1912, so that there was a possibility of an epidemic developing. In order to prevent this there should be a most careful scrutiny of all doubtful cases. Warning should be taken from the fearful experience of enteric fever among the recruits in America on the occasion of the Spanish-American war, when it was recognised that the disease was not so much water-borne, but was conveyed by fingers, food, and flies. The same record had been met with in most campaigns, and notably in the South African war. So far as the present war was concerned there was no record of any serious disability from enteric fever. He was unable to give definite information, but judging from cases received from the front in the Oxford base hospital it could not be very frequent, as he had only noted two or three cases. Yet all the time the conditions of the war were such as would naturally predispose to an outbreak of the disease, and under these conditions he considered that it would be a great triumph for sanitation if no devastating outbreak of enteric fever were experienced during the war.

---

[3] THE LANCET, Nov. 14th 1914 p. 1161

The President congratulated Sir William Osler on his contribution to the important subject under discussion, and expressed his strong belief in antityphoid inoculation. He quoted statistics to show the great improvement which had taken place in the health of the Indian army since this had been introduced. He regarded the problem of typhoid carriers as a very serious one, and in India isolation stations were arranged for convalescents from typhoid who still retained the infection. Paratyphoid cases were also very troublesome, many of them becoming chronic carriers.

Sir John Broadbent referred to the insidious character of paratyphoid and the frequency with which this might be conveyed by carriers. He pleaded for greater care in dealing with the problem of the excreta in camps at home, and recommended the S.O.S. system, which not only rendered sewage innocuous but made it possible for it to be utilised.

Dr. Walter Broadbent stated that he had investigated six cases of illness after inoculation at Brighton. The first was one in which an attack of pneumonia supervened the day after the first dose of vaccine, and terminated fatally on the seventh day. Although the patient was feeling unwell he did not lie up, and so caught a chill and developed pneumonia. In the next series of four cases feverish symptoms developed six to eight days after the second dose of vaccine. Feverish symptoms persisted for some days, but in the end recovery was complete. These men were inoculated on the same day, and perhaps there might have been some defect in the vaccine. In the sixth case the symptoms of fever came on two days after the second dose of vaccine. He also appeared to be doing well when last seen.

Dr. E. W. Goodall, after referring to the conclusive results of inoculation, expressed disappointment that they had not received more detailed news from the front. France and Belgium had been regarded as lands in which enteric fever was particularly rife. He had treated Belgian cases, but found it very difficult to obtain reliable particulars, though reference had been made to the existence in France of special typhoid wards. He was somewhat sceptical as to the importance of typhoid carriers, but believed that the danger of personal infection should be recognised.

Dr. G. Newton Pitt referred to an attack of sclerotitis occurring after inoculation as might happen in a case of gonorrhœa.

Fleet-Surgeon P. W. Bassett-Smith, speaking from the naval point of view, stated that inoculation was widely used in the navy. He knew of a case where a typhoid carrier was the means of carrying enteric fever from one ship to another.

Dr. J. M. Atkinson thought men were sent to the front too soon after inoculation, and gave instances of influenza and albuminuria which had come on after inoculation.

Dr. F. M. Sandwith questioned whether the deltoid region was the best site for inoculation. He had performed more than 1000 inoculations without any untoward results, and he believed that such ill-effects when they occurred were due to failure to take care after inoculation. He quoted a case where several men who had been inoculated were allowed to go for a route march the next day and consequently fainted. There should be 24 to 36 hours' rest after each inoculation. Segregation was of great importance in the treatment of enteric fever, and in the matter of the disposal of sewage he recommended the use of an incinerator. Carriers were specially important in India.

Dr. R. A. O'Brien alluded to a method of using slaked lime to disinfect typhoid stools. One tablespoonful of slaked lime was added to a cupful of boiling water, which generated sufficient heat to destroy bacilli. He had noticed records of outbreaks of enteric fever among German troops at Lille and Roubaix. This was an interesting fact when it was realised that the Germans had somewhat despised English methods of dealing with the disease.

Sir William Osler, in reply, referred to the suggestion that the rehearsing of cases of illness following inoculation might deter people from submitting to it. He contended that the people should be told the full truth, and that in the end they would trust in their medical advisers. Few therapeutic measures, even such as hypodermic injections, were devoid of all risk, yet they were not neglected on that account. He considered that the problem of the disposal of sewage was a most urgent one, and he was glad that medical officers of health throughout the country had the matter in hand. As to the question of carriers, the danger arose when the individual had to deal with food—e.g., a cook. He agreed with Dr. Sandwith that the deltoid region was not the best for the inoculation. He preferred the pectoral region or the abdominal wall. He was interested in the system of disinfection mentioned by Dr. O'Brien. Referring to the case of sclerotitis he mentioned a case of monarticular rheumatism which appeared to be very similar to a gonorrhœal attack. He agreed also that men should not be sent to the front too soon after inoculation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Exhibition of Specimens.—The Heart and Kidneys in Pregnancy.

A meeting of this section was held on Oct. 30th, Dr. M. J. Gibson, the President, being in the chair.

Dr. Gibbon FitzGibbon showed a Uterus with Malignant Adenoma removed from an unmarried patient, aged 60, who had been told when 35 years of age that she had a fibroid and advised not to have it removed. Menstruation was always normal, and the menopause occurred at 48 normally. Since then there had been no bleeding or discharge until seven months before being first seen by Dr. FitzGibbon. Bleeding had then occurred and lasted 14 days, and had been recurring irregularly ever since, and sometimes profusely. On examination the uterus was uniformly enlarged, about the size of a four months' pregnancy, somewhat soft, and the cervix small and atrophic. The diagnosis was myoma, probably undergoing some degeneration. After laparotomy and panhysterectomy the patient made an excellent recovery. The specimen showed a soft cauliflower growth filling up the cavity of the uterus and growing all over the walls, which were very thick, about 1¼ inches. Sections of the growth showed typical adenoma with very marked malignant characters in some parts, and invading the wall of the uterus. The cervix was quite free from invasion.—Sir William Smyly said there could be little doubt that it was a myoma which had been invaded by a cancer.—Dr. R. J. Rowlette said the specimen appeared to him to be a carcinoma occurring in a uterus already the seat of a fibroid. Such an event was not uncommon where a fibroid gave rise to irritation of the endometrium.—The President said that since carcinoma of the body was commoner in cases where fibromyomata were present than in cases in which they were absent, and since degeneration of fibromyomata was most usual after the menopause, it was necessary to abandon the opinion that after the menopause fibromyomata were not likely to give trouble.

Dr. B. Solomons showed a Fibroid Uterus from an unmarried woman aged 27, who came to hospital complaining of uterine hæmorrhage. On examination fibroid uterus was diagnosed, though the uterus was quite smooth and felt like an ordinary myometritis. Palliative curettage and styptic treatment were carried out, but the hæmorrhage recurred, and she returned to the hospital. The abdomen was opened in the hope of performing myomectomy, but when the uterus was opened it was found to be studded with myomata, some submucous, others interstitial, and hysterectomy was done. The case showed how impossible it was to promise myomectomy.—Mr. S. SHEILL considered that the most important point about the specimen was the early history.—The PRESIDENT considered that hysterectomy was the only course which could have been adopted in this case.

Dr. V. J. MCALLISTER gave a summary of the various conditions of the heart which might influence pregnancy, and the forms of renal lesions which might pre-exist or occur during pregnancy.—Sir WILLIAM SMYLY said that in practice one had to go according to symptoms much more than physical signs; if the heart was competent it might be left alone, but if it became incompetent it would be necessary to try to restore it by strophanthus and digitalis, and if not successful the patient should be delivered. He always advocated that in case of kidney disease which did not improve under treatment the uterus should be emptied.—Dr. E. HASTINGS TWEEDY said he held that all the pathological conditions found in association with toxæmia arose as a consequence of the poison, and in no instance was the poisoned state the result of the kidney lesions. He was glad to understand that the deleterious influence of milk and other foods had become recognised, at all events in Dublin, as a causal agency in eclamptic fits. He was convinced that foodstuffs acted as partial poisons to almost all pregnant women, which accounted for the presence of morning sickness. A tolerance against these food poisons became established in most instances, but when this was not so acute toxæmic degeneration resulted.—Dr. W. M. CROFTON said that in certain cases of eclampsia he had found the urine badly infected with micro-organisms. It might be well to examine the urine bacteriologically in order to see if this was a common occurrence. In pregnancy there was usually great hypertrophy of the suprarenals, and if the secretion of these was unbalanced this might be a cause of the high blood pressure.—Dr. SOLOMONS said that everybody seemed to accept the food theory as advanced by Dr. Tweedy. He mentioned a case of eclampsia where the patient was well for 24 hours, but when milk was given a fatal result ensued.—The PRESIDENT said that he had seen a certain amount of trouble, even in ordinary uncomplicated disease of the heart. The increase of blood pressure during pregnancy or labour told on a diseased heart. In cases of the toxæmia of pregnancy he considered the blood pressure of great importance. He failed to see how food could produce the toxæmia of pregnancy, but when toxæmia was present food, and particularly milk, should be withheld until the toxæmia had definitely decreased.—Dr. MCALLISTER, in reply, referred, among other points raised, to the relationship between blood pressure and eclampsia. He considered it more favourable for a patient to have a moderately high blood pressure if she had or was going to get eclampsia. He thought that possibly many patients did not get eclampsia because their blood pressure was high.

HUNTERIAN SOCIETY.—A meeting of this society was held on Nov. 11th at the Barbers' Hall, Dr. T. Glover Lyon, the President, being in the chair.—Dr. Alexander Morison read a paper on Pernicious Anæmia. He said that the exact discrimination of pernicious anæmia was possible only after careful examination of the blood picture. Alone among anæmias it showed a great reduction of total red blood cells, a large proportion of megalocytes, a high colour index, and usually a reduction and never an excess of white cells. After death there was always in the liver, and usually in the spleen and kidneys, a peculiar deposit of iron rendered visible to the naked eye by a special test. The onset was probably insidious in every case, an apparently acute onset being a culmination, not a commencement, and corresponding to a septic phase in the disease. The termination was uniformly fatal. Functional disturbances, due to abnormalities in the blood-supply, appeared first, organic lesions later on. Superficial extravasation was never extensive; small visceral extravasation had been detected on microscopic examination after death. The disease might be due to a blood destruction or to a disorder of blood production. The constant features of the condition would suggest a constant cause. Dr. William Hunter assigned an oro-gastro-intestinal origin to the disease, but sepsis of the digestive tract was common, and pernicious anæmia was rare. The establishment of a specific bacterial, protozoic or toxic cause would favour the view of hæmolytic origin. Some thought the disease due to a faulty elaboration of the blood. The notable deposit of hæmosiderin would thus be due to the presence of an excess of megaloblasts and megalocytes, not to excessive blood destruction, the cause of the disease being not necessarily from without or toxic, but none the less a malignant one, which was preventing normal blood development. After rest and fresh air, treatment consisted in the rectification of errors in mouth, stomach, and intestine. Arsenic, either in inorganic form or as salvarsan, held out the best hope. The latter was preferable when the patient was under constant observation, the inorganic form being given afterwards in small doses. He had used salvarsan mostly in 0·2 gm. doses (=1/13 grain arsenic) suspended in oil given intramuscularly every week, or 0·4 gm. every fortnight; benefit was usually but not always marked. He had never succeeded in raising the red cells to 5,000,000. The effect of arsenic in promoting the elaboration of blood was attributable to its stimulation of the blood-producing organs, either directly or through the nervous system.—Mr. A. White Robertson, in a paper on the Master Toxin, said that our knowledge of the processes at work in any toxæmia was inadequate and fallacious without a knowledge of the serological and cytological state of the blood. It was to the white cells and not the red that we must first look for information of a toxic condition of the blood. He had been able from a simple blood examination to identify in cases with widely differing symptoms the master toxin, whose subversive agency had allowed the development of the secondary invasions. Recurrent malaria, especially of the subtertian type, not only masked many subsequent diseases, but actually laid the patient open to them. Similarly, it was well recognised that gonorrhœa and syphilis were followed by loss of resistance to other infections. In his opinion measles, whooping-cough, and influenza, no less than exposure, accident, and mental shock, acted frequently as neuro-depressants and predisposed to tuberculosis and the many other bacterial disorders, even perhaps after a period of years. Our duty, then, must be to realise that the after-treatment of these neurotoxic conditions was, if possible, of greater importance than that of the immediate symptoms. After long study of the blood changes in tuberculosis, he had concluded that if the master toxin were recognised and dealt with, the disease was entirely curable by a direct immunising process. The master toxin arose from the coli group, and X ray examination confirmed the presence of intestinal stasis. Recent investigations were opening out a wider conception of the influence of these master toxins, as witness recent papers by Mr. Rupert Farrant on the thyroid,[1] and the results of Sir Arbuthnot Lane's abdominal surgery in such different sequelæ of stasis as tuberculous hip-joint, goitre, and Raynaud's disease.[2] He had lately begun to have a suspicion that there might be some connexion between the mutant coli group and pernicious anæmia. We might yet come to insist upon X ray examination of the gastro-intestinal tract in this disease. He would like to see such an examination made legally compulsory before any case of dementia was transferred to an asylum.—The papers were discussed by Dr. W. Langdon Brown, Dr. Morison, Dr. O. K. Williamson, Dr. S. Russell Wells, and Dr. Mackenzie Wallis.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Nov. 13th, Mr. Herbert Jones, the President, being in the chair.—Dr. W. J. Howarth read a paper on the Marking of Meat. He said that in the term marking of meat he included the marking of the carcass either by certificate, label, seal, tag, stamp or brand, or by any other method, such mark to indicate that the meat had been examined and approved as fit for human consumption and to give information as to the date and place of inspection, and of the person making the inspection. About 18 years ago the question of marking meat was under consideration in a fairly acute form owing to the development of the colonial meat trade. Since then the importation of live animals had practically ceased and there had been an enormous increase in the chilled and frozen meat trade which had become centralised until it was now almost entirely in the hands of large firms who had gradually improved their work by the application of better methods and had brought the quality of imported meat up to a high standard. Home-grown meat always had been, and still was, the best meat, and the arguments in favour of marking were mainly that it prevented substitution. Definite proofs of injurious effects resulting from the partaking of unsound meat had not been common—a fact that was possibly due in this country to the general custom of cooking meat, though it could not be denied that real dangers did exist. The actual nutritive value of meat should be considered, and more attention was now directed to this than was formerly the case. Meat should not only be sound but should possess a distinct nutritive value. To mark meat after examination of the carcass alone would be a retrograde step, if for no other reason than that such an examination would in many instances be unreliable. The only place where a really satisfactory and reliable decision as to the suitability of a carcass for human consumption could be made was at the place of slaughter, when every organ was available for inspection. The want of uniformity in meat inspection and the deficient facilities for inspection would render a general compulsory system of meat marking impracticable at the present time, but considerable advantage would be derived if some form of optional marking could be devised. The Local Government Board should be requested officially to approve a system of meat marking, and should decide upon the nature of the mark and the manner of marking, and take steps to safeguard the use of the mark only by a recognised authority. The power to use the mark should only be granted on request and after the Board was satisfied that satisfactory inspection of meat was in force in the district concerned.—Dr. R. Veitch Clark considered that the private slaughter-houses increased the difficulties connected with the control of meat supplies. Although he thought that in the course of time an extensive system of meat marking would have to be adopted, he was of opinion that the time was hardly ripe for the development of an optional scheme. Experience in Leeds had shown that stricter inspection resulted in indifferent meat being sent to be sold outside the town.—Dr. W. A. Bond agreed that the marking of meat even on an optional basis was very desirable.—Dr. G. Buchan feared that optional marking would press hardly on the honest butcher, and he advocated the giving of compensation to the butcher who bought an animal in good faith which was subsequently condemned as unsatisfactory.—The President pointed out that the question of meat marking was altogether bound up with that of the abolition of private slaughter-houses. He was not convinced that any system of optional marking would be either practicable or desirable, though he was in favour of the adoption of a general and uniform scheme for the whole country.

[2] THE LANCET, March 15th, 1913, p. 755.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 4th, Dr. W. R. Smith, the President, being in the chair.—Dr. C. H. Cattle gave a lantern demonstration illustrating Irregularity of the Heart-beat. Reference was made to the great advances in our knowledge of this subject due chiefly to the clinical and experimental investigations in this country of Dr. J. Mackenzie and Dr. T. Lewis. The classification of irregularities now generally adopted followed the lines laid down in the well-known works of those writers. Among the more common forms of cardiac disorder referred to were the following:—(1) Sinus arrhythmia, or the youthful type of irregularity; (2) delayed conductivity and heart-block; (3) premature contraction of auricle or ventricle; (4) tachycardia with regular or irregular rhythm; (5) auricular flutter and auricular fibrillation; and (6) exhausted contractility and pulsus alternans. Tracings were shown illustrating the normal and abnormal forms of venous pulse, and reasons were given for the change of type during auricular fibrillation. It was also shown how the different forms of cardiac irregularity may be differentiated both by means of the polygraph and other clinical methods. Valuable as the graphic method undoubtedly is, its results must always be taken in connexion with a complete survey of all the clinical features of a case. An attempt was made to explain the action of digitalis, and illustrations were shown of its effect in slowing the heart and occasioning coupled beats.

Reviews and Notices of Books.

The Curves of Life: Being an Account of Spiral Formations and their Application to Growth in Nature, to Science, and to Art, with Special Reference to the Manuscripts of Leonardo da Vinci.

By THEODORE ANDREA COOK, M.A., F.S.A. With 11 plates and 415 illustrations. London: Constable and Co., Limited. 1914. Pp. 479. Price 12*s.* 6*d.* net.

MORE than 20 years ago the author, after a long visit to the banks of the Loire, produced for the inspection of some distinguished biologists a photograph of the inside of the open staircase at Blois, showing the spiral lines carved on the central column and the vaulting, when the late Professor Charles Stewart "loudly proclaimed his recognition of the spiral curves therein depicted," and asserted that "the curves upon its central columella were identical with those of *Voluta vespertilio.*" The shell was fetched, "a longitudinal incision was made, and the four-fold spiral revealed within upon the columella. In spite of many other conflicting interests and duties," says the author, "I have thought of that chance discovery ever since." The result is a wonderfully suggestive volume, with its profusion of beautiful and appropriate illustrations culled from organic and inorganic nature and from some of the masterpieces of art to show that "with very few exceptions the spiral formation is intimately connected with the phenomena of life and growth." The author, having an intimate knowledge of the work of Leonardo da Vinci, enters into a critical exposition of the evidence which leads him to the conclusion that the name of the unknown architect of the left-hand spiral staircase in Blois was none other than Leonardo himself.

As the author's investigations on "spirality" broadened—and they ranged amongst living forms from the microscopical foraminifera and spirilla to the nautilus, which most closely approximates to a logarithmic spiral—aid was required to pursue the subject. With the assistance of expert authorities in separate divisions of research he has now presented in well-reasoned and suggestive chapters, supported by many literary references, an array of facts to illustrate the prevalence of the spiral in natural structure and phenomena. As these facts arrange themselves in his mind, a mind keenly alive to resemblances and differences between things, they lead him to suggest on occasion some remarkable analogies.

The range of subjects dealt with is so varied that even students of anatomy and morphology will find new light thrown upon familiar phenomena. After giving an account of the growth and beauty of spiral formations and the simpler mathematics of the subject, the author urges that nature and art are never mathematical, yet he is ever in pursuit of "sequences of events" to which mathematical expression can be applied. Every department of knowledge has been laid under contribution; spiral nebulæ, clouds, and whirlwinds, crystals, screws, the "mirror writing" of Leonardo, spiral eddies in dust and smoke, upright and flat spirals in shells, all come in for comment; and spiral leaf arrangements, phyllotaxis, climbing plants, right-hand and left-hand spiral growth in plants, spirals in horns, and spirals in human and animal anatomy are discussed. Mr. Cook traces spiral decoration onwards from prehistoric times, through ancient civilisations to the modern era. Some principles of growth and beauty are lucidly explained by references to the works of Dürer, Dante, Leonardo, and Goethe, while in architecture the author finds a subject in which he delights to instruct us from an obviously first-hand and intimate acquaintance with the subject.

Mr. Cook has written this book with sincere conviction of the truth of his views, and while not agreeing with some of the deductions we most highly commend the exceedingly interesting, and in many cases unconventional, manner in which he has done his work. He has let in much light on obscure problems and added a fascination to the study of "spirality" in art and nature. To medical men Chapter XIII., on spiral formations in the human body, will prove particularly interesting and in some respects quite novel.

A Manual of Surgery for Students and Practitioners.

By FRANCIS T. STEWART, M.D., Professor of Clinical Surgery, Jefferson Medical College. Third edition. With 571 illustrations. London: J. and A. Churchill. Pp. 742. Price 16*s*. net.

THE text-books of surgery are becoming very numerous, and there must be one to suit every taste. The work before us can be safely recommended to the student, though in the endeavour to compress the whole of surgery into a comparatively small compass the author has found it necessary to give somewhat brief accounts of many operations. The descriptions, however, are sufficiently long for most purposes, and the fact that it has been found advisable to include an account of gynæcological surgery in the volume also leaves less room for other portions of the subject.

There are many parts of the book which are especially good. We may mention the account of the interpretation of skiagrams; and this is of great importance, for many surgeons do not grasp the fact that the method in which a skiagram is taken has an enormous influence on the appearance shown, so that in a fracture it is possible to make the fragments appear to overlap or to have an interval between them according to the relative positions of the tube, the limb, and the plate. We should have liked to have the evidence on which the author bases the opinion that the value of iodoform in tuberculosis is due to the fact that the iodine formed irritates the tissues and so gives rise to the formation of fibrous tissue. We cannot agree with the author in the statement that the pigment in a melanotic sarcoma is sometimes due to the decomposition of extravasated blood. It is true that hæmorrhagic pigmentation may be seen in a sarcoma, but that does not make it a melanotic sarcoma; the two conditions are absolutely distinct. It is curious to meet with the statement that venereal warts may occur "spontaneously." It is being generally recognised now that all warts are microbic in origin, and that they are never the result of mere irritation, and certainly never occur spontaneously.

However, these are small points. The net impression given by reading the book is that it is a sound, practical, and comprehensive guide.

LIBRARY TABLE.

Field Ambulance Notes. By Captain M. F. GRANT, R.A.M.C. London: Forster, Groom, and Co. 1914. Pp. 146. Price 2*s*.—This little book appears opportunely, when so many medical men are setting themselves to study, and carry out in actual practice, the work of the army surgeon in the field. No one without considerable experience can carry in his head the various points of detail in regard to transport, equipment, and procedure which it is necessary for every medical officer actively employed to be acquainted with. In this pocket-book will be found collected from various sources all that concerns the mobilisation, organisation, equipment, &c., of field ambulances, clearly set forth in a form suitable for reference. It is quite up to date. Territorial Force Regulations are quoted when necessary, and in the last chapter a summary is given of the field ambulance equivalents in foreign armies.

Physics. Third edition, thoroughly revised and amplified, and containing an entirely new chapter on the electron theory and radio-activity. By C. G. KNOTT, D.Sc. Edin., F.R.S.E. London and Edinburgh: W. and R. Chambers. Pp. 370. Price 7*s*. 6*d*.—This is an excellent text-book which should admirably fulfil its purpose; it is intended for the use of junior students, and more especially medical students in their first year of study. The issue of the third edition has given the author the opportunity of adding a new chapter on the electron theory and radio-activity, while the book throughout shows evidence of revision and amplification in accordance with modern developments. The subject is divided into two parts, the first of which deals with matter and energy, and the second with matter, ether, and energy. In the former are the subsections (*a*) properties of matter, (*b*) heat, and (*c*) wave-motion, and in the latter (*a*) electricity and magnetism and (*b*) radiant energy. This plan presents a clear division of the general subject according to modern acceptations. The book is clearly written, and the references "to familiar facts of observation and to experiments of the simplest character" make it a real educational aid to the reader studying physics for the first time.

Medical and Pharmaceutical Latin for Students of Medicine and Pharmacy. By REGINALD R. BENNETT. With an introduction by HENRY G. GREENISH. Second edition. London: J. and A. Churchill. 1914. Pp. 443. Price 6*s*. 6*d*. net.—The first edition of this book was reviewed in THE LANCET of August 4th, 1906, and we then took occasion to share the regret expressed by Mr. Greenish, who contributes the introduction, on the gradual abandonment of Latin as the language of prescription writing. The principal changes in the present edition consist in a careful revision and some rearrangement of certain sections, while more modern prescriptions have on occasion been substituted for older ones, and the vocabularies have been enlarged by the inclusion of recent terms of medical and pharmaceutical nomenclature. On p. 5 carbasus and alvus, two feminine nouns, are included without warning in the list of masculine nouns of the second declension, though the gender of both is given rightly in the Latin vocabulary.

Physical Chemistry, its Bearing on Biology and Medicine. By JAMES C. PHILIP, M.A., Ph.D., D.Sc. Second edition. London: Edward Arnold.

Pp. 326. Price 7*s.* 6*d.* net.—The importance of a knowledge of physico-chemical principles when dealing with great biological questions has become more and more obvious during recent years. The study of biochemistry has in fact become an essential in the medical curriculum, and considerable progress has been made in medical science by the application of physico-chemical principles. We have only to refer to a selection among the chapters in this useful book to find what an important bearing the subjects therein treated have on physiological processes. For example, we may mention osmotic pressure, permeability and impermeability of membranes, electrolytic dissociation, colloidal solutions, adsorption, and so forth. The story is set out just as it should be for students of medicine, who will find here clearly stated examples of the application of physico-chemical principles taken from the fields of biology, physiology, and medicine. This second edition brings the work up to date, as is evident from the references to recent work.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., Professor ALEX. MACALISTER, Professor ARTHUR THOMSON, Professor ARTHUR KEITH, and Professor ARTHUR ROBINSON. Vol. XLIX. Third Series. Vol. X., Part I. October, 1914. London: Charles Griffin and Co., Limited. Annual subscription 21*s.*, post free. —Two articles, both dealing with the descriptive anatomy of early human embryos, occupy most of the space in the present issue. The first of these, by Mr. H. L. Barniville, was carried out in Professor Wiedersheim's laboratory, and deals with an embryo of 8·5 mm. The paper is a remarkably exhaustive one and well illustrated, and it furnishes an extremely useful record of the condition of development at this stage. There are several points of special interest connected with Mr. Barniville's description of the organs and parts of this embryo. In particular we would note the suggestive condition of the cæcal region, and the bearing of the state of the parts upon the work of von Berenberg-Gossler, whose views the author adopts. The work is extremely thorough, and it is a little depressing to note how few British works are quoted in the copious bibliography. The second contribution to human embryology is by Professor David Waterston, and it deals with an embryo of 2·9 mm. This embryo is at an interesting stage of development, and the description makes a good landmark in the progress of formation of human organs. Professor Waterston lays special emphasis upon the heart and pericardium, and for the other systems he gives a summary of the conditions met with. These two papers make interesting reading when taken side by side, and the reader will find much to arrest his attention and compel thought. We note that Professor Waterston estimates the age of his embryo at somewhere near 30 days, while Mr. Barniville places his at 35.—Dr. J. S. B. Stopford contributes a paper upon the Supracondyloid Tubercles of the Femur. The communication points out the precise origin of the medial head of the gastrocnemius. The paper was wanted, for there is much incorrect teaching at present upon this point.—Professor J. A. Pires de Lima, of Oporto, describes a case of Bifid Penis with Penial Hypospadia. The case is not a common one and is of interest. The explanation of its development as given by the author is obviously the true one.—Mr. J. Wilfrid Jackson discusses the Dental Mutilations in Neolithic Human Remains. The neolithic skulls he describes are those discovered by himself in Dog Holes, Lancashire. The mutilation consists in the removal of upper central incisors and lower second premolars, practices very similar to those indulged in by many races to-day.

Malaria e Malattie dei Paesi Caldi. Anno V., Fasc. IV. August 20th, 1914. Rome: Via Farini 62.—This number contains a further communication by Professor Tizzoni and Dr. A. de Angelis on the Streptobacillus of Pellagra in which they explain the reason of the polymorphism shown by this organism previously described by them, and prove the relationship between it and the lower hyphomycetes. Dr. A. Gasbarrini gives his experiences of the Wassermann reaction in cases of malaria. He examined 43 cases, and obtained a positive result in 18·6 per cent. The reaction generally disappeared a few days after the defervescence of fever, but its intensity had no relation with the presence and variety of the plasmodia circulating in the blood nor with their number. In latent malaria the reaction was always negative.—Dr. F. Scordo discusses the nature of certain granular bodies recently described by Wenyon in kala-azar. He is of opinion that since these bodies are often absent in cases of typical Leishmaniosis, their appearance may be due to a collective degeneration of the parasites caused by some hitherto unknown reason.—Professor Ilvento and Dr. Mazzitelli describe the cases of plague treated at Tripoli from June to September, 1913. Under the heading Pesticæmia are the cases of two infants at the breast of plague-stricken mothers, one of whom died. The sudden and unexpected death of the children without any apparent lesion excited suspicion, and blood obtained by aspiration from the heart of the corpse gave positive microscopic and cultural evidence of Yersin's bacillus. With regard to therapeutic measures intravenous injections of corrosive sublimate were used in three cases without appreciable advantage. Subcutaneous injections of electrargol were resorted to in five cases and were followed invariably by an improvement in the general symptoms. The last 17 cases were treated by peribubonic injections of solution of iodine 1 centigramme in 2 cubic centimetres of solution of iodide of potassium, four subcutaneous doses of half a cubic centimetre being given daily. While intraglandular injections of iodine aggravated the local and general symptoms, this periglandular treatment, combined with the application of ice, was well tolerated. All the cases thus treated, even after the appearance of grave initial symptoms, exhibited a rapid improvement in general symptoms and abortive febrile course.

The Dental Record.—The November issue contains a paper on the Treatment of Root Canals, by F. D. Lamb. The author considers that many of the unsuccessful results are due to lack of care in carrying out the cleansing and filling of the canals. He discusses in a critical manner several of the methods usually adopted. There is a translation from *La Revue de Stomatologie* (April, 1914) of a paper by Pierre Robin, on the eruption of the deciduous and permanent dentition. A graphic table is given, but the data are open to criticism. An account is given of an unusual type of maxillary cyst arising in connexion with the left permanent canine, the root of which had pierced the floor of the orbit.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 19th, Sir Francis H. Champneys being in the chair. A letter was considered from the clerk to the guardians of the Walsall union with regard to the resolution of the Board refusing to admit to examination a candidate who had tendered a birth certificate which had been tampered with. The Board directed that the clerk to the guardians of the Walsall union be informed that the Board regrets that it is unable to condone the serious offence of which the candidate has been guilty. It is willing, however, to allow her to apply again in October, 1915, on forwarding evidence satisfactory to the Board that she appreciates the gravity of her offence and is resolved to behave honestly in future. A letter was considered from the clerk of the Bucks county council asking whether the local supervising authority has any jurisdiction over a certified midwife when acting in the capacity of a nurse under a medical practitioner in attendance on a confinement. The Board decided that the clerk of the Bucks county council be informed that a midwife acting only as a nurse is amenable to the Act and also to some of the rules (e.g., Rule E.5), but not to all. A letter was considered from a certified midwife, who was approved by the Board at its last meeting to undertake the training of pupil midwives, asking whether the qualifying 15 lectures may be spread over a period of seven weeks only. The Board directed that the approval of this midwife be suspended until the Board has satisfied itself that she knows and is prepared to carry out the rules of the Board.

# Reports and Analytical Records
FROM
THE LANCET LABORATORY.

1) "TABLOID" HEXAMINE; (2) "TABLOID" SODIUM ACID PHOSPHATE.

(BURROUGHS WELLCOME AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

1. Hexamine is the name now officially given to hexa-methylene-tetramine in the new British Pharmacopœia. It is accepted as a useful diuretic, uric acid solvent, and antiseptic. The above firm actually manufacture the substance at their works at Dartford, Kent, and the refined product answering the official tests of purity is issued in tabloid form containing either 3 or 5 grains of hexamine. 2. The tabloid sodium acid phosphate is designed for use in conjunction with hexamine, the activity of which it encourages by increasing the acidity of the urine. The combination is thus useful in the treatment of cystitis, gonorrhœa, and other infective diseases of the genito-urinary tract.

JEYSOL.

(JEYES' SANITARY COMPOUNDS COMPANY, LIMITED, 64, CANNON-STREET, LONDON, E.C.)

This is a well-prepared combination of fatty acids and alkali with powerful germicidal tar acids. It is perfectly clear and mixes in all proportions with water, forming an alkaline bright solution. We found approximately 50 per cent. of tar acids present, and according to their iodine value it is obvious to us that very effective tar derivatives (from a germicidal point of view) have been used for the purpose. In other words, the chemical indications are in favour of a satisfactory carbolic coefficient, having regard to the fact that the preparation mixes perfectly with water and does not form an emulsion. Its cleansing and detergent properties should render it of particular value in surgery, while in convenient dilutions it may be used with good results in the treatment of infective throat troubles.

HÆ-MO-PHOSPH.

(THE HÆ-MO-PHOSPH MANUFACTURING COMPANY, SHELTON, STOKE-ON-TRENT).

Hæmophosph is a dark brownish-red somewhat viscid fluid which on analysis shows distinctly the presence of hæmoglobin and of coagulable albumin. Clinical reports appear to have established the value of this preparation as a hæmatinic. Shortly, it may be described as a tonic food of service in enfeebled conditions. According to our analysis it contains 23·81 per cent. of solid matters, and mineral matter 1·48 per cent. On heating the fluid coagulation of the albumin results, and we find that this amounts to 18·71 per cent. A dilute solution of hæmophosph when examined spectroscopically showed the well-known absorption bands of hæmoglobin.

OXFORD MARMALADE.

(FRANK COOPER, OXFORD.

We may accept the assurance that this marmalade is prepared with care and made from superior materials inasmuch as it is of attractive consistence and the flavour of the Seville orange is well preserved. Its dark colour is due no doubt to considerable boiling. Those who make marmalade at home as a rule forget that a superior product is always obtained by prolonged boiling. We examined the marmalade for objectionable preservatives, but with negative results. Analysis gave the following figures: total sugar, 55·55 per cent.; moisture, 38·59 per cent.; orange skin tissue, 5·53 per cent.; mineral matter, 0·33 per cent. Marmalade is a favourite adjunct at the breakfast table, and there is no doubt of its wholesomeness.

ANTISEPTIC WATERPROOF MATERIAL.

(JAMES SPICER AND SONS, 50, UPPER THAMES-STREET, LONDON, E.C.)

Our attention has been called to this material as likely to supply a demand at the present crisis for an economical waterproof material for bandages and bedsheets in the place of oil silk and rubber fabric. We have examined this material and are able to confirm the claims made in regard to it. It appears to be ordinary wrapping paper made waterproof by a film of waxy material. On steeping the paper in alcohol the waterproofing substance is removed. The material is not damaged, we find, by the ordinary fluid antiseptics used in surgery, but iodine leaves an apparently indelible stain. We certainly agree that this material would be of great service, especially at a time of colossal necessity.

TOXOL.

(MESSRS. BOOTS, STATION-STREET, NOTTINGHAM.)

Toxol is a clear dark brown fluid representing a careful combination of cresols with oil soap. We separated the cresols from the soap by means of the baryta method and the yield was approximately 55 per cent. of cresols by volume. The cresols chosen for the preparation are evidently of high germicidal power, judging from their chemical characteristics. The iodine combination value indicated a carbolic coefficient of at least three. The preparation should be of service where an efficient disinfectant as well as detergent is required.

HOOKER'S MALTED MILK.

(THEW, HOOKER, AND GILBEY, 6, HOLBORN VIADUCT, LONDON, E.C.)

The effect of the enzymes of malt upon milk in rendering it decidedly more easy of digestion is very evident in this preparation. The dry powder forms with water a regular emulsion with a milky appearance, the fat thus being evenly distributed. On adding acid to the fluid a copious coagulation of casein takes place, but it does not separate in curds but in fine particles. This is a valuable characteristic in infant feeding. According to our examination the preparation still shows enzymic activity and is quite free from starch. Its flavour is pleasantly malty and milky. Our analysis was as follows: Moisture, 1·50 per cent.; mineral salts, 3·50 per cent.; maltose and lactose, 55·80 per cent.; dextrine, 16·00 per cent.; protein, 14·00 per cent.; and fat, 9·20 per cent. From these figures it will be seen that this preparation furnishes a complete food which, owing to its careful method of production, is readily assimilated. Over 80 per cent. of the preparation is soluble in warm water.

HETROFORM.

(CHARLES ZIMMERMANN AND CO. (CHEMICALS), LIMITED, 9 AND 10, ST. MARY-AT-HILL, LONDON, E.C.)

Hetroform is described as an improved urinary antiseptic. It is, in fact, a compound of hexa-methylene-tetramine with benzoic acid. The object of such a combination is obvious, for in the urinary passages both antiseptics, formaldehyde and benzoic acid, are slowly set free. Further, the urine assumes an acid reaction.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE thirtieth annual meeting of Fellows and Members of the Royal College of Surgeons of England was held at the College, Lincoln's Inn-fields, W.C., on Nov. 19th. Sir W. WATSON CHEYNE, the President, took the chair, and was supported by Sir Frederic Eve, senior Vice-President, Sir Rickman Godlee, the late President, and 4 other members of the Council. There were also present 6 other Fellows and 41 Members.

The PRESIDENT placed before the meeting the annual report of the Council for the year ending August 1st, 1914, which was reviewed in THE LANCET of Oct. 31st, and stated that copies had been circulated to 951 Fellows and 2629 Members. He briefly indicated some of the main features in the report, and answered certain questions put to him by Dr. Sidney C. Lawrence, honorary secretary of the Society of Members of the Royal College of Surgeons of England.

Sir VICTOR HORSLEY then moved the following resolution standing in his name:—

> That this thirtieth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College, which as now constituted only represents those Members who also hold the Fellowship, and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

Sir Victor Horsley blamed the Council for its contemptuous indifference to the repeated demand for representation by Members expressed at previous annual meetings, and criticised generally the policy and attitude of the governing body of the College.

Dr. GEORGE JONES, barrister-at law, who seconded the motion in a persuasive speech, urged the Council to look ahead and make friends now with the large body of Members, so that it might have behind it their support in dealing with the difficult questions which the future held in store. He referred in particular to the growing competition by provincial universities, and concluded by advising the Members to make their watchwords in the struggle for regaining their right of representation, "educate, agitate, organise."

Among those who also spoke in favour of the resolution were Mr. W. J. MIDELTON, who deplored the breach which he said existed between Fellows and Members of the College; Mr. J. BRINDLEY-JAMES, who offered a hearty personal welcome to the new President; Dr. SIDNEY LAWRENCE, who referred to the satisfactory progress made during the past year by the Society of Members; and Mr. J. G. FITZGERALD.

After Sir VICTOR HORSLEY had briefly replied to the discussion, the resolution was put to the meeting and declared carried *nemine contradicente*, and the proceedings closed with a vote of thanks to the President, carried with acclamation.

ASYLUM REPORTS.

Hereford County and City Lunatic Asylum (Annual Report for the Year 1913).—The total number of patients under treatment during the year was 566, the average daily number being 502. There were 58 direct admissions. The chief causative factor was alcohol in 7 cases, syphilis in 6, and insane heredity in 6. There was no case of general paralysis. The number of discharges was 25, with a recovery percentage of 35·4 on the total admissions. Mr. C. S. Morrison, the medical superintendent, remarks that many of the patients under treatment during the year would undoubtedly have derived benefit from open-air treatment on verandahs, if such conveniences had been available. The deaths numbered 23, the mortality based on the average daily number resident being 4·6 per cent., as against 8·7 last year. Pulmonary tuberculosis was responsible for 5 deaths, and Mr. Morrison states that tuberculous disease is much too prevalent, and that provision of recognised means for treatment and to reduce the risks of infection should not be long postponed. He also notes the rise in the weekly cost from 8*s*. 9*d*. per head in 1909 to 10*s*. 6*d*. in 1913. This is due to many factors which influence the expenditure in public institutions. The general sense of the community is directed towards levelling up institutions to a standard giving larger benefits to employees, and better differentiated care to those deriving advantage from the provision of such institutions. The increasing cost of necessaries and the advance in wages add their quota annually to the general rise.

Baldovan Institution (near Dundee) for the Treatment and Education of the Feeble-minded (Annual Report for the Year 1913).—The number of children who passed through the institution during the year was 240. There were 42 admissions and 15 discharges. The deaths numbered 17. The causes of death were in 2 instances epilepsy, in 2 tuberculous disease, in 2 pneumonia, in 1 asthenia, and in 1 scarlet fever and epilepsy. Of the 208 children resident, 82 attended school and received there teaching fitted for their several requirements. A new departure has been made which will permit of some 14 boys working at joinery. Plans have been made during the last few years for the removal of the more educable children from among the more degenerate. With this end in view alterations and rearrangements of the buildings have been carried out which give increased accommodation and make supervision easier. It is now possible to effect a complete separation between those who can only be nursed and those who are capable of being taught.

THE Chelsea Hospital for Women has received from the executors of the will of the late Mr. Thomas Stephen Whitaker the sum of £2000 towards the rebuilding of the hospital.

DORSET MEMORIAL TO THE LATE KING.—A meeting was held at Dorchester recently in connexion with the Dorset King Edward Memorial Fund, under the presidency of Lord Ilchester. The sum of £1610 has been raised, and it was decided to invest this and divide the interest between the Dorset County Home for Nurses and the Dorset County Nursing Association.

THE VENICE MEDICAL POST-GRADUATE COURSE.—The Medical Association of Venice has announced the suspension of the post-graduate course usually held in the month of November. The grounds given are the uncertain conditions in which the medical profession finds itself at present owing to the political situation, and the hope is expressed that it may be possible to hold the course next spring.

ROYAL SUSSEX COUNTY HOSPITAL.—Additional open-air balconies have been added at the Royal Sussex County Hospital at Brighton, the latest additions to the septic wards of the York block being erected by the generosity of Major-General Marsland. The balconies are on two floors, the upper one being used for female and the lower for male patients. The cost of erection was over £600. The balconies were formally opened on Nov. 11th, Dr. W. Furner, on behalf of the medical staff, expressing the deep appreciation of the generous gift.

EAST SUSSEX AND THE MENTALLY DEFECTIVE.—The committee dealing with the mentally defective in East Sussex has presented a scheme to the county council for providing an institution for women and girls, and boys under 12, at an initial outlay of £4550. Mainly on account of the growing expenditure in other directions and the war, the scheme was strongly opposed and was thrown out by 34 votes to 7. The proposal provided for the reception of 100 patients, whereas the committee at the present time has only six cases, for the placing out of which it is paying 10*s*. 6*d*. a week per head.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 28, 1914.

The War and the Standard of Medical Education.

THE General Medical Council are sitting this week at their 100th session, and Sir DONALD MACALISTER, in referring to the fact in his presidential address, said that if the meeting had been held in different historical circumstances he might have been tempted to improve the occasion by offering some reflections on the past history of the Council, but that he would refrain because the new history that was in the making was too urgent to leave room for indulgence in such retrospect. The rest of his interesting address was largely occupied in demonstrating the active part which the Council had taken in meeting the national emergencies that have arisen, and that will arise, in connexion with the civil and military medical service during the war—emergencies that must affect the medical profession deeply, as they have a direct bearing upon its numerical strength, as they may prejudice its ordinary work as guardians of the health of the population at large, and as, if care be not taken, they may influence for the worse the standards of scientific education.

Sir DONALD MACALISTER dealt with the last of these points first, and alluded to communications which had been received by the Council from various professional authorities inquiring as to the propriety of modifying or suspending some of the existing regulations in the case of students whose regular course of study for a medical qualification might be interrupted by reason of military service. As it was known that some of the licensing bodies proposed to hold special examinations to meet the case of candidates who had completed the curriculum and were desirous of offering themselves without delay for medical military service, it is obvious that the Council was invited to deal here with a situation which might imply some lowering of the standard of proficiency among qualified men, the maintenance of which is one of the great statutory duties of the Council. The Council met the situation with firmness and discretion, and with what we may describe as a military grasp of the situation, refusing to make everything easy for everybody because the country was at war. Exactly as the military authorities will not admit to the terrible responsibility of meeting the enemy in the field, men who have not undergone adequate training for the task, so the General Medical Council set its face from the first against any lowering of the tests for admission to the roll of qualified men, lest the care of the soldier in his sore need, or of the civil population, should fall into insufficiently instructed hands. While recognising that there was a very distinct call, the call of the national need, for a number of young qualified medical men, the Council has insisted also on the paramount necessity in the public interest of maintaining unimpaired the due standard of efficiency required of all who seek enrolment upon the Medical Register with the status and privileges which follow thereon. The Council formulated recommendations as a guide to the various licensing bodies with regard to modifications of the curriculum, so that the course of training might be speeded up, and these bodies have one and all given effect to the views of the Council by regulations of their own.

With regard to the number of medical men who have offered themselves for service under the Crown either in this country or with the Expeditionary Forces, no certain figure is available, but it is known that the number is a very large one, and that there are a great many medical men whose offers of service have not as yet been accepted, the difficulty being to allot them exactly in places where their assistance is most required. We all of us hear both sides of this matter, and know that the military authorities on the one hand are seeking particular medical officers to be employed in one direction, while medical men hoping to serve their country in other than these capacities have been disappointed, but this situation is, we believe, gradually disappearing. A difficulty has also arisen with regard to those medical men who are with the colours. The depletion of the staffs of the general hospitals of the country all over the kingdom has been marked owing to the mobilisation of the Territorial Forces, while the dislocation of private practice following upon the same cause remains grave; indeed, if the public health of the country just now were not good the situation would be one of considerable anxiety. The subject is briefly touched upon by Sir DONALD MACALISTER in his address, and has several times been alluded to in these columns, where we have announced our belief that this position, being now appreciated by the War Office, will be met by simpler methods of adjustment. The efforts of Sir DONALD MACALISTER in this direction have been strenuous, and now that the first pressure of military and general organisation has been met they should bear fruit. In the meantime, although it is many of our own readers whom we are praising to their faces, we think it right to call attention to the fine and generous spirit towards each other which medical men all over the country have shown in dealing with the problems arising out of the compulsory desertion of practices. On all sides we find a desire among the practitioners remaining behind to maintain and protect the interests of their absent colleagues.

Enteric Fever Prevention in Civil and Military Life.

IT has been said, to emphasise a sanitary moral, that it is fortunate for this country that neither bacillus carriers nor antityphoid vaccine were discovered earlier than they were. Enteric fever prevalence in the United Kingdom has been steadily falling for the last 50 years, and is now only about an eighth of what it was in the "seventies" of the last century. This reduction has been partly secured by greater attention to prophylaxis in respect of the sick persons themselves, but is chiefly to be attributed to wider measures of "sanitation." These measures are not directed against known enteric fever infection as such, but aim at the removal of excremental contamination of water, food, and soil, however this may occur, regardless of the question whether the contamination is from healthy persons, from enteric fever cases, or from carriers of the typhoid bacillus. Dangerous water-supplies, cesspools, privies, unpaved yards, sewage-polluted shell-fish and foods, and a host of other matters coming within the purview of general sanitation, have been dealt with principally on account of their proved association with enteric fever, to the great benefit of the community in many directions besides the diminution effected in this one disease. On the other hand, the "new" methods against enteric fever adopted in other countries which are less advanced in general sanitation are more specific and depend primarily on bacteriological methods enabling the individual enteric fever case or typhoid carrier to be detected and controlled. Such methods have been applied abroad with great thoroughness and success, the most conspicuous example being the great "antityphoid" campaign conducted in recent years in Alsace, but we have no hesitation in regarding our own as the better way.

At home the mischief done by the individual carrier is occasionally serious and perhaps enough to warrant restrictive measures being taken in exceptional cases against particular individuals; but such action under normal conditions of civil life should be only incidental and subsidiary to the general methods which have been so fully justified by experience. In camps and armies on service, however (as Sir WILLIAM OSLER insisted in his recent address to the Society of Tropical Medicine), the several methods of prophylaxis assume different relative values, particularly when the country in military occupation is one in which enteric fever is normally endemic. The conditions of active service in which disastrous results might follow from infection by incipient cases of enteric fever or by the presence of carriers among the troops can easily be apprehended. Medical opinion is thus practically unanimous that every soldier on service ought to obtain the effective protection which antityphoid inoculation can give, and supports any precautions which are practically feasible for the elimination of the carrier from our armies. It should, however, go without saying that reliance on antityphoid inoculation and other new measures ought not to involve any slackening in the efforts to secure good general sanitation for the troops. Apart from the consideration that the duration of the protection conferred by the inoculation is relatively transient, the general measures of good military hygiene not only give protection against enteric fever, but also have a much wider influence on the health of the soldier. In our home camps and billets there is no essential reason, if proper care be taken, why troops should be any more exposed to the results of excremental contamination of water, food, or soil than was the case when the same men were in civil life. Even if every soldier were inoculated against typhoid infection, sanitary organisation would still need to be encouraged to the utmost in our new armies, and education in personal hygiene and methods of cleanliness must continue to be regarded as among the most important parts of the military training of our troops.

Annotations.

"Ne quid nimis."

THE MEDICAL INSURANCE AGENCY.

AN interim report on the progress of the Medical Insurance Agency for the nine months ending Sept. 30th was presented by the chairman, Dr. G. E. Haslip, to a meeting of the committee on Nov. 5th. The Agency had, he stated, not escaped the effects of the war, the receipts for new life and motor-car business especially having been adversely affected, although the commission on life business effected antecedent to the war had very nearly doubled during the period under review. On the other hand, a substantial business in war risks had been negotiated, and had helped to make good any shrinkage in other classes of business. The surplus shown by the auditor's figures would, the chairman said, justify the distribution to medical charities of the sum of 300 guineas for the current year, and it was resolved accordingly to make contributions to the Royal Medical Benevolent Fund (100 guineas), the Royal Medical Benevolent Fund Guild (50 guineas), Epsom College Benevolent Fund (75 guineas), the Royal Medical Benevolent Fund Society of Ireland (25 guineas), THE LANCET Editor's Fund (15 guineas), the Royal St. Anne's School (10 guineas), and, provisionally, to the fund for distressed Belgian medical men (25 guineas). The subscription to the Royal St. Anne's School was made with the specific object of assisting daughters of medical men in obtaining election to that school. Altogether the Agency since it was instituted has voted a sum of £1075 to medical charities, and, in addition, it has returned to insurers a sum of over £3000. The Agency is prepared to undertake to arrange policies for insurances of all kinds, and from the experience already gained it is able to advise medical men as to the best form of policies, and as to their satisfactory adjustment to meet the varying needs of individuals. Further particulars can be obtained on application to the agent and secretary, Medical Insurance Agency, care of British Medical Association, 429, Strand, London, W.C. The committee of management consists of Dr. G. E. Haslip (chairman), Dr. Alfred Cox, Mr. Guy Elliston, Sir Frederick Hewitt, M.V.O., Dr. H. A. Latimer, Dr. J. A. Macdonald, Dr. D. J. Mackintosh, M.V.O., Mr. H. Betham Robinson, M.S., Dr. S. Squire Sprigge, and Dr. Dawson Williams.

MYELOID SARCOMA.

IN another part of this issue of THE LANCET is published an important paper on myeloid sarcoma by Dr. Matthew J. Stewart, of Leeds. This remarkable new growth has received no small degree of attention during the last few years, and it has formed one of the main topics in a discussion on sarcoma at the Royal Society of Medicine.[1] The point in which this variety of tumour differs from all other forms of sarcoma is its very low degree of malignancy. All other varieties of sarcoma are very malignant, and especially malignant are the sarcomata of bone; the myeloid sarcomata have hardly any malignancy—in fact, it is not going too far to say that they are not malignant at all. They never affect the neighbouring lymphatic glands, yet this may also be said of some other kinds of sarcoma. More important still is the fact that the myeloid sarcoma never in any circumstances gives rise to secondary growths in other parts of the body, though with ordinary sarcomata of bone death is nearly always due to the formation of secondary growths. Indeed, it is only from the fact that the myeloid sarcoma has a tendency to recur locally that it can be said to be malignant at all, but this local recurrence means nothing more than that it has not been completely removed. It is certainly not encapsuled, and there is no sharp dividing line between the growth and the surrounding tissues. Yet in numberless instances recurrence has not occurred after the local removal of a myeloid sarcoma, and even when a recurrence has taken place a second attempt at removal has generally succeeded. Clinically, therefore, the myeloid sarcomata behave very differently from the other new growths with which they are usually classed; they are for all practical purposes non-malignant tumours. This difference has been so keenly felt by some pathologists that they have preferred to call the myeloid sarcoma by a name which would not suggest any relation to the sarcomata, and so the word myeloma has been widely employed. With the name of myeloma, however, Dr. Stewart cannot agree. He acknowledges that clinically these growths are different—that they do not act like malignant growths, but he feels compelled to class them as embryonic connective tissue growths, and therefore he says that they must be sarcomata, and not unaptly he points out an analogy in the position of rodent ulcer in the carcinomata; it is certainly a carcinoma, but clinically its malignancy is very slight. The claim that a myeloma is a sarcoma depends then on its histological structure, and not on its clinical characters, and it is to the histology of these growths that Dr. Stewart's paper is chiefly devoted. While pointing out the resemblances between the myeloma and the other sarcomata, he shows that it is always possible by the microscope to distinguish easily between the myeloma and the malignant giant-celled sarcoma, which at the first glance resembles it. He shows that in the myeloid sarcoma the nuclei are numerous, uniform, small, and without mitoses; while in the malignant giant-cell sarcoma the nuclei are few, irregular, and large, and mitotic figures are common. On the certainty of the value of this histological difference depends the importance of this study; for on the microscopic characters depends the treatment. In a definite myeloid sarcoma the surgeon may with confidence practise free local removal; and the results of the examination of the cases which Dr. Stewart has studied and in which local removal has been performed show that of 40 cases traced 38 are alive at the present time, and that in one only of these is there local recurrence. Dr. Stewart's paper is a careful study of an important subject, and it will afford valuable support to the growing practice of the local treatment of myeloid sarcomata.

"NOSTALGIE MILITAIRE."

NOSTALGIA as a specific disease especially afflicting recruits has never figured in English text-books of medicine or mental disease, but our French allies had up to about the year 1877 issued a whole literature on the subject. Switzerland, as we are informed by Jean Jacques Rousseau, was the original home of what was long regarded as a dangerous malady. The Swiss, he asserts, were forbidden to listen to the music of the Ranz-des-Vaches if it happened to be played to them when on the march, since the monotonous strains, associated in their minds with home and the mountains, led to desertions, sickness, and death. Johannes Hofer, a Mulhouse physician, is perhaps the original authority on *mal du pays*, which he calls "pothopatridalgia." His book was published in Basle in 1688. He speaks of a specific disease, tells many stories of its extraordinarily fatal results, and transcribes in quaint notation the music of the Ranz-des-Vaches, or Kuh-Reihen, to the sound of which he directly traces his "pothopatridalgia." As years pass the picturesque element in home sickness becomes modified, and in 1837 we find the subject treated at great length and with a complete appearance of scientific justice by Paulinier in a Montpellier thesis. He describes the pallor, taciturnity, absolute dejection, loss of appetite, and so forth, which attack the recruit suffering from home sickness, and adds the curious observation that in the great wars of the French Republic the illness was unknown owing to the enthusiasm of the soldiers for France, every inch of which had become home in their regard. Later, when the Napoleonic wars had sapped the vitality of the nation, the condition of *mal du pays* became almost epidemic among the boy recruits of 1812 and the following years. There is little to choose between Paulinier's views and those of many of his successors. They all describe much the same set of symptoms. Writing as lately as February, 1863, an American army surgeon, De Witt C. Peters, speaks of the incidence of this form of melancholia among young recruits drawn from the Eastern States of the Union and sent to fight in the, to them, enervating climate of the south. "The hospitals of New Orleans," he says, "during the past summer were filled with such cases. ...... The majority of them were young men from the Eastern States, whose love of home and kindred is a characteristic trait." His definition of the symptoms tallies with that of his predecessors.

---

[1] THE LANCET, Nov. 16th (p. 1362) and 23rd (p. 1435), 1912.

"The symptoms produced by this aberration of mind are, first, great mental dejection, loss of appetite, indifference to external influences, irregular action of the bowels, and slight hectic fever. As the disease progresses it is attended by hysterical weeping, a dull pain in the head, throbbing of the temporal arteries, anxious expression of the face, watchfulness, and increased fever and wasting. Among young prisoners of war it is the worst complication to be encountered, as the writer can truthfully affirm." We can only trust that as our allies and ourselves are fighting with high hopes in an inspiring cause such a form of mental depression is unknown or rare among them. The Italians speak familiarly of nostalgia as a disease of recruits.

DUODENAL ULCER IN INFANCY.

DUODENAL ulcer has rarely been observed in infancy. An American writer, Holt, recently could find recorded only 91 cases in the first year of life, to which he added four cases from a total of 1800 necropsies at the Babies' Hospital, New York. In the *American Journal of the Medical Sciences* for November Dr. B. S. Veeder has published an important paper on the subject based on the experience of the Department of Pediatrics, Washington University Medical School, and the St. Louis Children's Hospital. His statistics indicate a greater frequency of duodenal ulcer in children than those given above. During the last two years five cases were observed in one hospital in St. Louis. From the pathological standpoint the condition was found four times in 62 necropsies on infants under one year. From the clinical standpoint it was diagnosed four times among 586 admissions to the infant ward and 2000 infants under 1 year treated at the out-patients' department. The following is an example. A female, aged 1 month, was admitted on March 20th, 1912. She was born at term, was breast-fed for two weeks, and then fed on condensed milk, 1 in 16. This was well taken for two weeks, but then was refused, and the stools became loose and watery. Two hours before admission she was put on barley water, which was refused. On the day of admission she passed four loose mucous stools and vomited once. Milk diluted with three parts of water and protein milk were tried without benefit. On March 30th black granular material was vomited, and soon afterwards a tarry stool was passed. The temperature remained continuously subnormal, but there were no signs of collapse. Duodenal ulcer was diagnosed. Two days later more tarry stools were passed. She gradually became weaker and died on April 5th. The necropsy showed an irregular ulcer measuring 7·5 by 5 mm. on the posterior wall of the duodenum just beyond the pylorus. The margins were elevated and undermined. Near this ulcer was another 3 mm. in diameter. The ulcers extended through the mucosa and submucosa, and their bases were covered with greyish slough. In 4 out of the 5 cases there was a fairly typical picture of duodenal ulcer from which the diagnosis could be made, and it was confirmed by necropsy in 3 which were fatal. All the infants were under 6 months and were artificially fed and marasmic, but 3 had received a fair start on breast feeding. Vomiting occurred in all the cases and was a marked feature in 3. Melæna was present in 4 cases. In the absence of the subjective symptoms, which are so important in the adult, the diagnosis depends upon the few objective symptoms given above. Gross hæmorrhage from the bowel is the only definite symptom pointing to duodenal ulcer; when absent the diagnosis cannot be made. Acute ulcerative conditions of the lower intestine must be excluded, but these are usually associated with acute nutritional disturbances. The prognosis is unfavourable because of the age of the patients and the associated chronic malnutrition. As to the treatment, the only indication is to place the infant under the best nutritional conditions, which means breast feeding. The pathology is obscure. The ulcers may be single or multiple. They vary from small areas of superficial necrosis to punched-out ulcers involving all the intestinal coats, and in a few cases causing perforation. They are found between the pylorus and the ampulla of Vater, most commonly just beyond the pyloric ring. In practically all the cases they were on the posterior wall. This seems to be due to the fact that such position is the most dependent part of the duodenum when the infant is on its back, and therefore the place where any substance acting on the mucosa would be most likely to produce an effect. The ulceration appears to be in some way due to intestinal decomposition. This is most common in the early months of infancy, and most of the subjects were in the first five months of infancy.

NON-TUBERCULOUS LESIONS OF THE PULMONARY APEX.

As comparatively little attention has been given to disease of the apex of the lung which cannot be attributed to tubercle, we welcome a communication on this subject made by Dr. L. Devoto to the Twenty-fourth Italian Medical Congress at Genoa last month and reproduced in a recent number of *Il Morgagni*. The author first draws attention to cases which simulate a morbid condition of the apices which really does not exist. For example, in young children a limited and persistent unilateral dulness is often found, leading to the suspicion of tuberculosis of the apex or tracheo-bronchial glands. Such dulness, however, is due to changes in the bony thorax, and particularly to slight deviations of the vertebral column, or to abnormal length of the apophysis of the cervical vertebræ. Moreover, it is not unusual to meet with patients who for some months present a subfebrile temperature of uncertain origin. With the idea of tubercle present it requires care and judgment to avoid an error in diagnosis. By violent coughing and forced respiration it is easy to provoke the formation of a râle, especially if the examination be made in the morning after the patient has remained for a considerable time in a supine posture in bed. It is, moreover, stated that in the course of chronic appendicitis moist sounds may be heard at the apices, which disappear when the local process becomes more marked. Then there are the chlorotic girls, with slight dulness at one apex, a harsh vesicular murmur, prolonged expiration, loss of flesh, and debility, who are sent to the sanatorium only to be dismissed after a short time because the physical signs at the apex have no relation with tubercle but with the asthenia of chlorosis. Having cleared the ground of what might seem to indicate, owing to errors of observation or interpretation, a diseased condition of the apices, the author enters upon apical pathology properly so-called. Among primary conditions of the apex which are not tuberculous he draws attention to apical pleurisy, either dry or with serous or purulent effusion, simple bronchial catarrh, bronchiolo-alveolitis and peribronchitis from inhalation of dust, bronchopulmonary foci occurring as sequelæ of influenza, whooping-cough, diphtheria or typhoid fever, pneumonomycosis, new growths and gummata, abscess, and bronchial concretions. Passing on to secondary affections of the apex, the author notices that physical signs of collapse at the right apex are met with in persons suffering from diseases of the upper air-passages, and that in aged people with torpid circulation a diminution of resonance and moist sounds are found at one or both apices. Similar conditions, the result of toxæmia or weakened circulation, are found in uræmia, diabetes, polysarcia, and in the course of severe nephritis, in the induration following an apical pneumonia and pulmonary infarcts. In the majority of cases non-tuberculous lesions of the apex can be clearly recognised. If by modern methods of investigation the non-tuberculous origin and nature of an apical lesion cannot be demonstrated, a tuberculous process is to be suspected, even if search for the bacillus and other special investigations give negative results. But this contingency of having to admit the tuberculous nature of a lesion by a process of exclusion is so rare that a diagnosis of tubercle arrived at by this means will be justified by the consideration that, within certain limits, diagnosis in excess is less prejudicial than diagnosis in default.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING IN LONDON.

A MEETING of the committee to organise a Relief Fund for Belgian Doctors and Pharmacists was held at the offices of the British Medical Association on Tuesday afternoon, Nov. 24th. The meeting arose out of invitations sent by the previously existing provisional committee, in order that it might transform itself at the first opportunity into a really representative body, which should give its influence to the movement to relieve in some way the misery of the Belgian doctors and pharmacists. The following were present:—

*Sir Rickman Godlee, Bart., in the Chair.
Sir Donald MacAlister, K.C.B., President of the General Medical Council.
Sir Henry Morris, Bart., Joint Treasurer of the General Medical Council.
*Sir Thomas Barlow, Bart., President of the Royal College of Physicians of London.
*Sir W. Watson Cheyne, Bart., President of the Royal College of Surgeons of England.
*Mr. Meredith Townsend, Master of the Apothecaries' Society of London.
Sir John W. Moore, late President of the Royal College of Physicians of Ireland.
Mr. James Hodsdon, President of the Royal College of Surgeons of Edinburgh.
Sir Lambert H. Ormsby, late President of the Royal College of Surgeons in Ireland.
*Dr. Frederick Taylor, President of the Royal Society of Medicine.
*Mr. W. J. Uglow Woolcock, Secretary and Registrar of the Pharmaceutical Society.
Sir Clifford Allbutt, K.C.B., Professor of Medicine in the University of Cambridge.
Sir Thomas Fraser, Professor of Materia Medica and Clinical Medicine in the University of Edinburgh.
Sir Charles Ball, Bart., Professor of Surgery in the University of Dublin.
Professor Robert Saundby, Professor of Medicine in the University of Birmingham.
Professor William Russell, Professor of Clinical Medicine in the University of Edinburgh.
Sir W. Whitla, Professor of Materia Medica and Therapeutics, Queen's University, Belfast.
Professor John Yule Mackay, Principal of, and Professor of Anatomy in, University College, Dundee.
Professor G. Elliot Smith, Professor of Anatomy in the Victoria University of Manchester.
*Dr. F. M. Sandwith, Gresham Professor of Physic.
Dr. J. C. McVail, Crown Nominee on the General Medical Council.
Professor Arthur Thomson, Professor of Anatomy in the University of Oxford.
*Dr. Herbert Spencer, Obstetric Physician to University College Hospital, London.
*Sir Frederic Eve, Senior Surgeon to the London Hospital.
Dr. Richard Caton, Consulting Physician to the Liverpool Royal Infirmary.
Dr. Norman Walker, Treasurer of the Royal College of Physicians of Edinburgh.
Mr. H. A. Latimer, } Direct Representatives for
*Mr. T. Jenner Verrall, } England on the General
Dr. J. A. Macdonald, } Medical Council.
*Dr. Alfred Cox, Medical Secretary of the British Medical Association.
*Dr. Dawson Williams, Editor of the "British Medical Journal."
*Dr. H. A. Des Vœux (Honorary Treasurer).
*Dr. S. Squire Sprigge (Honorary Secretary), Editor of "The Lancet."

Those marked with an asterisk were members of the provisional committee, and were chosen by the meeting to form the executive committee.

The appended letter was approved for distribution to the press as an open appeal, and sufficiently explains both what has been done and what it is hoped to do. Hearty coöperation was promised both from Scotland and Ireland, and the committee has been strongly reinforced from both these divisions of the United Kingdom, and also by prominent members of the pharmaceutical profession.

IRISH SUPPORT.

A Belgian medical relief fund was started in Dublin some days ago. A letter from Professor Jacobs, of Brussels, having been received by the Presidents of the Irish Royal Colleges, asking for assistance for distressed Belgian medical men and pharmacists, the Presidents, after consultation with their respective Colleges, summoned a meeting of the medical profession of Dublin. The meeting was held on Nov. 20th in the Royal College of Physicians of Ireland, the President in the chair. The first resolution, moved by Mr. F. Conway Dwyer, President of the Royal College of Surgeons in Ireland, and seconded by Dr. James Little, senior Fellow of the Royal College of Physicians of Ireland, expressed sympathy with the Belgian medical profession, and authorised the opening of a fund for their relief. A further resolution, establishing a committee for the purpose of carrying the first resolution into effect, was proposed by Dr. Joseph O'Carroll, Vice-President of the Royal College of Physicians, and seconded by Mr. William Taylor, Vice-President of the Royal College of Surgeons. Promises and subscriptions amounting to nearly £300 were received after the meeting.

THE OPEN APPEAL.

SIR,—A provisional committee was formed recently to assist in any way that was found possible Belgian doctors and pharmacists, both those remaining in Belgium and those who are refugees in this country, who are involved in utter distress. A statement received from Professor Jacobs, of Brussels University, acting as the spokesman of a Belgian committee with similar aims, has already been published,[1] and certain measures were taken immediately by the provisional committee, who, in announcing what had been done, recognised that the scope for further effort was enormous, and that the provisional committee ought to be reinforced forthwith by representatives of medicine and pharmacy in England, Ireland, Scotland, and Wales.

As a result a strong committee has been formally constituted. It includes representatives of the medical faculties of the Universities, of the great medical and pharmaceutical Corporations, of the General Medical Council, and of the British Medical Association, and the activities of that committee will be limited only by the amount of money and material placed at its disposal, and by the exigencies of the political situation.

The committee is aware that great efforts are being made in numerous directions for the assistance of the Belgian refugees and Belgian people generally, but feels that it will be the pleasure and is, indeed, the duty of medical men and pharmacists to help the medical and pharmaceutical professions of Belgium. The movement is one undertaken by doctors and pharmacists on behalf of the Belgian doctors and pharmacists.

The committee has placed before itself a double programme: (1) to distribute what help it can at the present moment; and (2) to collect funds for the assistance of Belgian medical men and pharmacists in the future.

(1) As a tentative measure 50 packets of drugs and dressings are under order for despatch to Belgium. This will test the precautions which are being taken to ensure that the goods despatched will reach their destination and that they will be used by those only for whom they are intended—that is, the Belgian physicians and surgeons. In the second direction it is hoped to coöperate usefully with the general measures being adopted to succour Belgian doctors and pharmacists in this country.

(2) It is clear that no definite steps can be taken as yet for the rehabilitation of the medical and pharmaceutical professions in Belgium. A considerable sum of money will be required to replace ruined laboratories and pharmacies and to reestablish the ordinary course of medical administration, but nothing can be done now. It is intended, however, to communicate with the United States of America and other neutral countries, as well as with the Allied Nations, so that an international movement may be set up to reinstate the two professions.

But the committee feels that the uncertainty which exists with regard to the fulfilment of the second part of the programme should not prevent immediate and strenuous action in the spheres open to its work. The result of an experimental consignment to Belgium of medical stores will be known shortly, and if, as there is every reason to anticipate, the result is good, such consignments will be made regularly in accordance with the amount of money forthcoming. The committee has evidence that at least 2000 such packets as have already been arranged for are sorely needed, while each packet costs £5, the price being only kept down to this figure by the willingness of Messrs. Burroughs Wellcome and Co. to forego all profit.

At the same time the committee is aware of grave distress among the refugee medical men and pharmacists, and it feels that the organisations for succouring the great mass of Belgian refugees ought to be especially supported in anything that can be done for the members of the two professions.

It appeals therefore for immediate assistance, and appends a list of the first subscriptions actually received. Numerous promises of help have been made, and the committee is much indebted to the facilities which have been afforded to it by the British Medical Association, at whose house (429, Strand) the meetings have been and will in future be held.—We are, Sir, yours faithfully,

RICKMAN J. GODLEE (*Chairman*).

H. A. DES VŒUX (*Honorary Treasurer*),

[1] THE LANCET, Nov. 21st, 1914, p. 1220.

"GAS GANGRENE."

THE following report, which we have received for publication from the Secretary of the War Office, has been jointly drawn up by Sir Anthony A. Bowlby, C.M.G., Colonel, A.M.S., Consulting Surgeon to the Forces Overseas, and Dr. J. Sydney Rowlands. The report is written from the Field Laboratory General Headquarters and dated Nov. 11th, 1914. It is mainly the result of work done at the clearing hospitals at the front, to which patients are taken within a few hours of being wounded. A copy of the report has been sent to the Director of Medical Services, but many of the conclusions and practical recommendations have already been conveyed to the hospitals verbally or by official communications, and attempts are being made at the Lister Institute in London to provide a suitable antitoxin.

Report on Gas Gangrene.

It seems advisable to briefly record the conclusions at which we have so far arrived on the spreading gangrene which has occurred amongst the wounded of all the armies now in France.

One of us (S.R.) has examined the condition bacteriologically, and this examination was carried out in the "Mobile Field Laboratory." In a typical case affecting the hand a bacillus was found which was isolated for examination. A culture of this, when inoculated into a guinea-pig, caused its death in 18 hours. Post mortem there was found a gangrenous cellulitis from which the inoculated organism was recovered. A second guinea-pig inoculated from this culture was sent to the Lister Institute. It arrived safely and died within a few hours of its arrival, thus affording abundance of fresh material for a more detailed examination than was possible under field conditions. An examination of the culture was meanwhile made in the field laboratory and the conclusion arrived at was that it was probably the specific organism of malignant œdema. Further examination made at the Lister Institute by Dr. C. J. Martin, F.R.S., and Dr. Arkwright inclined these observers to the view that the organism in question was identical with one that for some time was confused with that of malignant œdema, known as the bacillus of Ghon and Sach. This organism was originally obtained from a case of gangrene in the human subject. There are some ten different organisms that have been isolated from cases of gas gangrene in man, all of which are closely allied and have the common characteristic of being anaerobic spore-bearers. From other cases in the clearing hospitals at the front several more organisms of this group have been isolated and have been sent to the Lister Institute for confirmatory diagnosis.

A sample of earth from a trench was also examined. The inoculation of a few drops of water, in which this earth had been shaken up, into a guinea-pig killed the animal in 18 hours. Post mortem a similar gangrenous cellulitis was found. The animal was also found, like the guinea-pig inoculated from the gangrenous hand culture, to be infected throughout with a spore-bearing anaerobic organism belonging to the same group. It is reasonable to conclude, therefore, that the gangrene found amongst our wounded soldiers is directly due to infection introduced at the time of the wound, and this is especially likely to occur if muddy clothing has been carried in by the projectile or if earth has been carried in by the explosion. We are, therefore, of the opinion that the gangrene that occurs amongst the wounded is a "traumatic infection" and dates from the moment of the injury. It is solely due to infection from the soil, and is in no way related to sloughing phagedena, or so-called "hospital gangrene."

Clinical picture of gas gangrene.—In the cases we have seen the gangrene has always occurred in connexion with wounds of the extremities. We have not seen it in the head, neck, thorax, or abdomen.

Nature of projectile.—We have seen it in wounds from rifle, shrapnel, and fragments of shell.

Nature of wound.—We have seen it in both slight and very serious wounds, but a larger proportion of the serious wounds are affected by it, especially when large bones have been shattered and muscles extensively torn and extruded. We have seen it with and without fractures, and in a relatively large number of fractures of the femur.

Period of onset.—It is most noticeable that it always shows itself within the first few days or even hours following the infliction of the injury. In two cases we have seen it well marked within 36 hours, and in several others already extensive on the third and fourth day. Several patients have died of it on the third day following that of the injury, and in other patients it has progressed so far that amputation has been performed on the third day.

Onset.—This is characterised by swelling of the injured part, and the gangrene seems especially liable to occur in connexion with that swelling of a limb which is due to extravasation of blood in the subcutaneous tissues and intermuscular planes. It seems to us that interference with the circulation either by extravasation of blood or by tight bandages has a marked influence. In the early stages the patient complains of severe pain which is perhaps due to tension, the result of the swelling, but in the later stages the affected area becomes completely numbed and insensitive. The edges of the wound are generally ragged and sloughy, and a considerable quantity of blood-stained serum constantly exudes and soaks the dressings. This discharge emits a characteristic and most offensive odour which is so marked as to be almost diagnostic. The skin, if not previously discoloured by extravasated blood, assumes a dark purplish or slate-coloured hue.

In the vicinity of the wound it changes subsequently to a more green colour. The swelling extends coincidently with the change of colour, and a few hours later the skin becomes nearly black, and finally forms a black, leathery slough. Beyond the area of discolouration the limb is swollen with gas and fluid exudation, and an emphysematous crackling can be elicited on pressure with the hand. This may spread to a distance of as much as a foot above and below the actually gangrenous area, and so rapid is the extension of the gangrene that we have seen the whole of the lower extremity completely mortified before the end of the third day after the infliction of the wound.

Condition of patient.—Temperature is not materially affected in many cases, and high fever is rare. A temperature of 99–100° is usual. Respiration is not materially quickened; headache is not complained of. The mind is perfectly clear till near the end. The pulse is not greatly quickened, but rapidly loses power, so that several of the patients we have seen have had no perceptible radial pulse. The heart's action is greatly weakened so that its beat is quite difficult to feel.

Vomiting is common and in many cases is frequent. Diarrhœa is rare. Sweating is not generally present, and before death the skin is cold. The tongue is usually covered with a dirty fur, but the mouth is not exceptionally dry. Death appears to be due to cardiac failure, and we have been struck by the extraordinary clearness of the mind of a patient, almost pulseless, and within an hour or two of his death. In the worst cases the gangrene may spread with such rapidity that the whole limb may be cold, of a purple or black colour, immensely swollen, and quite devoid of all sense of touch and power of motion within 36 hours of the onset of the gangrene. The smell of such a limb is overpowering and almost precludes a careful post-mortem examination. If incisions are made before or after death gas and sanious fluid bubble up.

Pus is confined to the edges of the wound, and is very little in proportion to the sanious discharge.

Conclusions.—The practical conclusions we would draw from these observations are as follows:—

1. All tight bandages, and especially those applied at the first field dressing, should be avoided. Shell wounds are so often followed by so much interstitial hæmorrhage that the part swells and the bandage rapidly becomes tighter and interferes with the circulation. Consequently many bandages require to be cut within a few hours of their application.

2. In many cases the tension requires to be relieved by incisions and drainage, and the opportunity should be taken to wash the wounds thoroughly with an antiseptic. Peroxide of hydrogen is one of the best. Great care should be taken to remove portions of clothing, as these contain the infective agent. Shattered fragments of bone and pieces of shell or gravel should be taken out.

3. Amputation may often be successfully performed through tissues made emphysematous by gas but not yet gangrenous.

4. The group of anaerobes causing gangrene are spore-bearers, and spores (especially of this group of anaerobes) are especially difficult to kill by any antiseptic solution or even by boiling. Consequently, in order to sterilise instruments and other things that have been infected other measures are required.

(*a*) Destruction of blankets and clothing soaked by the discharge.

(*b*) Heating in an autoclave at a temperature of 120° Centigrade.

(*c*) Boiling for an hour in a solution of 1/20 carbolic acid or lysol (1 in 10).

It should be remembered that the mud on the clothes of wounded soldiers is almost certainly infected, and care should be exercised to see that the area in which operations or dressing of wounds are performed should be kept free from possible contamination from such a source.

5. Where possible it is advisable to isolate patients under treatment in hospitals, and this is all the more necessary on account of the bad smell which is inseparable from the condition.

(Signed) ANTHONY A. BOWLBY.
SYDNEY ROWLANDS.

Field Laboratory, G.H.Q., Nov. 11th, 1914.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Deputy Inspector-General of Hospitals: R. F. Bown (retired) to the *Orion*. Fleet-Surgeon: M. H. Knapp to the *Pembroke*, additional, for disposal. Staff-Surgeon: G. D. Bateman to the *Victory*, additional, for the *Caroline*, and on commissioning. Surgeons: C. W. F. Greenhill to the *Columbine*, additional, for Queensferry Sick Quarters; P. B. Wallis to the *Pembroke*, additional, for disposal. Temporary Surgeons: M. H. de J. Harper to the *Pembroke*, additional, for duty in connexion with transport of wounded; J. Pratt to the *Victory*, for R.N. Division at Crystal Palace; and D. K. Adams to the *Vivid*, additional, for disposal.

ROYAL NAVAL RESERVE.

Rolf Creasy has been appointed Surgeon for temporary service in His Majesty's Fleet (dated Nov. 14th).

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon:—E. F. Murray to the *Victory*, additional, for the *Caroline*, to date Nov. 24th, and on commissioning, undated.

The undermentioned have been entered as Surgeon Probationers for temporary service: E. J. Coombe, A. G. McKee, D. H. Ferris, G. S. Barnett, J. Brooks, T. J. Lane, E. A. Leak, R. T. Stoney, M. R. Wallace, E. W. Drury, T. J. Sumner, G. E. Mullins, D. Heard, and W. P. Elford.

ARMY MEDICAL SERVICE.

William Tindall Lister to be temporary Colonel (dated Nov. 10th).

Lieutenant-Colonel Alfred P. Blenkinsop to be Assistant Director-General (dated Oct. 29th).

ROYAL ARMY MEDICAL CORPS.

Supernumerary Lieutenant-Colonel Charles H. Burtchaell is restored to the establishment (dated Oct. 29th).

William Allan Chapple to be temporary Major (dated Nov. 10th).

Supernumerary Captain George A. D. Harvey is restored to the establishment (dated Nov. 15th).

Percy Sargent to be Temporary Captain (dated Nov. 5th).

The undermentioned to be Temporary Lieutenants:—Dated Oct. 24th: John Charles Anderson. Dated Oct. 28th: Louis Cassidy. Dated Nov. 1st: Daniel McKelvey. Dated Nov. 2nd: Harry Vere White and Sydney Jacob. Dated Nov. 4th: William Fulton Neil, Gerald Woffanda Maw, Arthur Rennie Muir, William Brown Clark, Thomas Stanhope Gildea Martin, George Holmes Uvedale Corbett, Alexander Hunter, and Cecil Powell. Dated Nov. 5th: Robert Higham Cooper, Samuel McMurrich McLay, and Stewart Ranken Douglas. Dated Nov. 6th: Sydney Arthur Tucker, Julius Meyer Bernstein, and Millais Culpin. Dated Nov. 7th: John Thomas McCullagh, Alexander Johnston Couper, George Wilson Clark, Henry Maitland Moir, Evan Parry Evans, Courtenay Yorke, Laurence Thompson Dean, Henry Vernon Swindale, and John Stevenson. Dated Nov. 9th: Reginald John Hearn, Herbert Sidney Forsdike, Ernest Sydney Hawthorne, Alexander Keith Forbes, Idwal Jones Williams, Albert Latimer Walker, Henry Reginald Stanley Van Ryck de Groot, George Ford Petrie, and Herbert George Murdoch Henry. Dated Nov. 10th: Frederick Edward Wynne, Godfrey William Mitchell, Thomas Murray Newton, Lawrence Crombie, Sidney John Cullum, Joe Downes Yule, John Horace Dancy, Robert Charles Robertson, Albert Ernest Cotterill, Alfred Herbert James, Charles William Smith, Robert Craig, and John Louis Menzies. Dated Nov. 11th: Herbert Midgley Cockcroft, Andrew Gilmour, James McManus, and Bruce Alexander West. Dated Nov. 12th: Alexander Waugh Young.

The undermentioned Lieutenants relinquish their temporary commissions:—Dated Nov. 6th: James M. Renton and Robert S. Berry.

SUPPLEMENTARY TO REGULAR UNITS OR CORPS.

Royal Army Medical Corps.

The undermentioned to be Lieutenants (on probation): Dated Sept. 11th: John Rollo Noel Warburton. Dated Oct. 16th: William Clavering Hartgill. Dated Oct. 26th: Mathew McKnight. Dated Oct. 28th: John Smith Sloper. Dated Nov. 2nd: Hugh Alderson Fawcett. Dated Nov. 3rd: Arthur Lawrence Anthony, John Deighton, Cromwell Gamble, Herbert Leslie Garson, William Kerr Russell, John Hunter Sewart, Charles Grimshaw Waddington, George William Watson, Colin Wilson, and William Arthur Young. Dated Nov. 5th: Henry Scott Anderson Alexander. Dated Nov. 7th: James Robertson Cowper McIntosh, Harry Neville Stafford, and Wilfrid Westwood Phillips.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Richard Granville Waddy, from King Edward's Horse (The King's Oversea Dominions Regiment), to be Lieutenant.

TERRITORIAL FORCE.

Royal Army Medical Corps.

The undermentioned to be Lieutenants:—Rankine Greig Walker, Arthur Joseph Gordon Hunter, James Robertson Menzies (late Lieutenant, Edinburgh University Contingent, Senior Division, Officers Training Corps), William Henry Armistead (late Cadet Corporal, Edinburgh University Contingent, Senior Division, Officers Training Corps), Archibald Mathison Stewart (late Cadet, Edinburgh University Contingent, Senior Division, Officers Training Corps).

4th London Field Ambulance: Captain Thomas B. Layton, from the Unattached List for the Territorial Force, to be Captain (temporary). Alfred Richard Spencer to be Lieutenant.

5th London Field Ambulance: Captain Robert Corfe to be Major.

6th London Field Ambulance: Captain Norman C. Rutherford, from the Unattached List for the Territorial Force, to be Major (temporary).

1st London (City of London) General Hospital: Philip Hamill to be Captain.

2nd London (City of London) General Hospital: To be Captains: Gordon Wilkinson Goodhart and Archibald Douglas Reid.

1st London (City of London) Field Ambulance: Robert Williamson Asher Salmond to be Lieutenant.

3rd London (City of London) Field Ambulance: Thomas John Tyndale McHattie to be Captain. Robert Carswell to be Lieutenant.

1st London General Hospital: Captain Robert J. W. Oswald to be Major.

South Wales Mounted Brigade Field Ambulance: Major Herbert Jones, from the list of officers whose services are available on mobilisation, Sanitary Service, to be Major.

1st East Anglian Field Ambulance: Captain Lee D. B. Cogan, from Attached to other than Medical Units, to be Captain. Lieutenant Robert Ellis, from Attached to other than Medical Units, to be Lieutenant.

2nd East Anglian Field Ambulance: Herbert Vawdrey Capon (late Lieutenant, 2nd East Anglian Brigade, Royal Field Artillery) to be Lieutenant.

3rd East Anglian Field Ambulance: To be Lieutenants: Raymond Herbert Swindells and Mountague Adye Cholmeley (late Lieutenant, Royal Army Medical Corps (Militia)).

3rd Highland Field Ambulance: John George Anderson to be Lieutenant.

1st North Midland Field Ambulance: Hugh Agnew Macmillan to be Lieutenant. Thomas Stokoe Elliot to be Lieutenant.

2nd North Midland Field Ambulance: Bertram Sherrard Wills to be Lieutenant.

1st Northumbrian Field Ambulance: Hubert Shield to be Lieutenant.

1st West Riding Field Ambulance: Lieutenant Basil

Hughes, from Attached to Units other than Medical Units, to be Lieutenant.

London Mounted Brigade Field Ambulance: Lieutenant-Colonel (Honorary Major in the Army) Edmond James Lawless (late 23rd (County of London) Battalion, The London Regiment) to be Lieutenant-Colonel.

3rd Lowland Field Ambulance: Captain Henry Alfred Leebody to be Major (temporary). Clifford Halliday Kerr Smith (late Cadet, Edinburgh University Contingent, Senior Division, Officers Training Corps) to be Lieutenant.

1st Welsh Field Ambulance: William George Helsby to be Lieutenant.

2nd Western General Hospital: The undermentioned to be Lieutenants: Charles Harold Crawshaw, Edward Stanley Brentnall, and Frank Graham Wrigley.

2nd Wessex Field Ambulance: John Penn Milton to be Lieutenant.

2nd London Sanitary Company: Lieutenant William John More Slowan to be Captain (temporary). Ashley George Gyton Thompson to be Lieutenant.

Sanitary Service: Alexander Grant Russell Foulerton to be Captain on the List of Officers available on Mobilisation.

North Midland Clearing Hospital: The undermentioned to be Lieutenants: Montague Dixon, William Thomas Wood, David Dewar McNeill, Vincent Ackroyd Palliser Costobadie, George William Macbeath Andrew, and James Hugh Thomas.

Attached to Units other than Medical Units.—Captain Richard Brodie to be Major. Lieutenant David Dickie to be Captain. To be Lieutenants: Charles Donaldson Law, Charles Martin Mitchell, Archibald Hamilton, William Love, George Loraine Kerr Pringle, Arthur Errington Ridsdale (late Second Lieutenant, Sussex Imperial Yeomanry), Joseph Swinburn Townley (late Second Lieutenant, Brecknockshire Battalion, The South Wales Borderers), George Dingwall Thomson, Lieutenant Eliezer Coplans, from the 1st London (City of London) Field Ambulance, Arthur Jonas Friedlander, Gordon Whitehead, John Stephenson Clarke, Patrick Black, and Harry Greenwood Butterfield.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Lieutenant-Colonel James C. Renton, from 4th Scottish General Hospital, to be Lieutenant-Colonel.

EXAMINATION FOR ENTRY AS ACTING-SURGEONS, R.N.

Owing to the outbreak of war the course for Acting-Surgeons has been curtailed, the greater part of the Haslar course being eliminated, though the Greenwich course was completed. As a consequence the places of these gentlemen on the list of surgeons, R.N., has had to be assigned on the results of the Entrance Examination with the addition of the marks gained at the examination at the end of the Greenwich course. The marks obtained and the order of seniority are as follows:—

H. B. Parker	2488	W. F. Beattie	2113
J. L. Priston	2427	H. W. Fitzroy-Williams ...	2074
R. F. Quinton	2365	F. E. Fitzmaurice	2005
M. J. Aitken	2336	T. J. O'Riordan	1981
J. A. Maxwell	2267	J. C. Kelly	1970
M. S. Moore	2193	J. M. Horan	1886
W. G. Thwaytes*	—	G. M. Graham	1811
C. E. Greeson	2132	F. C. Hunot	1805

The Admiralty prizes were awarded as follows:—Gold medal, Surgeon H. B. Parker, formerly of the London Hospital; silver medal, Surgeon J. L. Priston, formerly of the London Hospital; Greenwich group prize (pocket instrument case), Surgeon J. L. Priston.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8097 births and 4966 deaths were registered during the week ended Saturday, Nov. 21st. The annual rate of mortality in these towns, which had declined from 13·8 to 13·0 per 1000 in the four preceding weeks, rose in the week under notice to 14·3 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 13·6, against 14·0 per 1000 in the metropolis. Among the several towns the death-rate last week ranged from 5·8 in Leyton and in Oxford, 5·9 in Hornsey, 6·7 in Bath, and 6·9 in Swindon, to 21·0 in Middlesbrough, 21·2 in Grimsby, 22·3 in Birkenhead, 22·4 in Rotherham, and 23·1 in Newcastle-on-Tyne.

The 4966 deaths from all causes were 449 in excess of the number in the previous week, and included 440 which were referred to the principal epidemic diseases, against 497 and 454 in the two preceding weeks. Of these 440 deaths, 148 resulted from measles, 138 from infantile diarrhœal diseases, 74 from diphtheria, 35 from whooping-cough, 28 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3 per 1000, and coincided with that recorded in the previous week. The deaths attributed to measles, which had increased from 67 to 167 in the five preceding weeks, fell to 148 last week, and caused the highest annual death-rates of 1·6 in Salford, 1·8 in Plymouth, 1·9 in Birkenhead, 2·4 in Rotherham, 2·6 in Gateshead, 2·8 in Wigan, 3·0 in Wakefield, and 3·4 in Newcastle-on-Tyne. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had steadily declined from 1223 to 131 in the nine preceding weeks, rose to 138 last week, and included 34 in London, 9 in Liverpool, 8 in Birmingham, 7 in Nottingham, and 6 each in Manchester, Sheffield, and Newcastle-on-Tyne. The fatal cases of diphtheria, which had been 61, 93, and 58 in the three preceding weeks, rose to 74 last week, of which 20 occurred in London, 4 each in Birmingham and Manchester, and 3 each in West Ham, Portsmouth, and Bristol. The deaths attributed to whooping-cough, which had been 32, 38, and 39 in the three preceding weeks, fell to 35 last week, and included 12 in London, 3 each in Liverpool and Newcastle-on-Tyne, and 2 in Bristol. The deaths referred to scarlet fever, which had been 38, 34, and 42 in the three preceding weeks, fell to 28 last week, of which 10 belonged to London, 5 to Manchester, and 2 each to Salford and Oldham. The fatal cases of enteric fever, which had been 14, 17, and 17 in the three preceding weeks, were again 17 last week, and included 3 in London and 2 each in Enfield, Southend-on Sea, and Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 4976 in the 13 preceding weeks, had further risen to 5005 on Saturday last; 627 new cases were admitted during the week, against 598, 690, and 751 in the three preceding weeks. These hospitals also contained on Saturday last 1631 cases of diphtheria, 66 of enteric fever, 59 of whooping-cough, and 54 of measles, but not one of small-pox. The 1264 deaths from all causes in London were 109 in excess of the number in the previous week, and corresponded to an annual death-rate of 14·6 per 1000. The deaths referred to diseases of the respiratory system, which had been 197, 193, and 181 in the three preceding weeks, rose to 203 in the week under notice, but were 3 below the number in the corresponding week of last year.

Of the 4966 deaths from all causes in the 97 towns, 187 resulted from different forms of violence and 393 were the subject of coroners' inquests, while 1446 occurred in public institutions. The causes of 57, or 1·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Salford, and in 48 other smaller towns. Of the 57 uncertified causes of death, 11 were registered in Birmingham, 9 in Liverpool, 3 in Hull, and 2 each in Southend-on-Sea, Bootle, Bradford, Sheffield, Darlington, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1099 births and 730 deaths were registered during the week ended Saturday, Nov. 21st. The annual rate of mortality in these towns, which had been 14·6, 15·8, and 15·2 per 1000 in the three preceding weeks, rose to 16·6 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 15·4, against 13·6 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 7·0 in Clydebank, 7·6 in Kirkcaldy, and 8·8 in Kilmarnock, to 18·8 in Falkirk, 22·5 in Dundee, and 23·5 in Leith.

The 730 deaths from all causes were 62 in excess of the number in the previous week, and included 69 which were referred to the principal epidemic diseases, against 79 and 50 in the two preceding weeks. Of these 69 deaths, 19 resulted from infantile diarrhœal diseases, 17 from diphtheria, 16 from scarlet fever, 13 from whooping-cough, and 2 each from enteric fever and measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·6, against 1·3 per 1000 in the 97 large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had declined from 31 to 20 in the four preceding weeks, were 19 last week, of which 6 belonged to Glasgow, 4 to Dundee, 3 to Edinburgh, and 2 to Aberdeen. The deaths referred to diphtheria, which had been 16, 18, and 7 in the three preceding weeks, rose to 17 last week, and included 9 in Glasgow, 4 in Edinburgh, and 2 in Aberdeen. The fatal cases of scarlet fever, which had been 14, 17, and 8 in the three preceding weeks, rose to 16 last week; 8 deaths were recorded in Glasgow, 3 in Aberdeen, and 2 each in Dundee and Paisley. The deaths attributed to whooping-cough, which had been 14, 12, and 7 in the three preceding weeks, increased to 13 last week, of which 9 belonged to Glasgow. The 2 fatal cases of enteric fever were registered in Glasgow, and those of measles in Glasgow and Dundee.

---

* Surgeon Thwaytes, through being seconded to the Royal Infirmary, Edinburgh, did not take the Greenwich course, and therefore has been allowed to take his original place in the London Entrance Examination, viz., seventh.

The deaths referred to diseases of the respiratory system, which had steadily increased from 62 to 111 in the nine preceding weeks, were 112 in the week under notice; 26 deaths resulted from different forms of violence, against 30 and 32 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 580 births and 423 deaths were registered during the week ended Saturday, Nov. 21st. The annual rate of mortality in these towns, which had been 15·2, 18·2, and 17·7 per 1000 in the three preceding weeks, rose to 18·3 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 16·7, against corresponding rates of 13·6 and 15·4 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 18·8 in Dublin (against 14·6 in London and 16·6 in Glasgow), 19·1 in Belfast, 27·9 in Cork, 15·2 in Londonderry, 6·8 in Limerick, and 13·3 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 13·5 per 1000.

The 423 deaths from all causes were 15 in excess of the numbers in the previous week, and included 44 which were referred to the principal epidemic diseases, against numbers declining from 51 to 40 in the three preceding weeks. Of these 44 deaths, 13 resulted from infantile diarrhœal diseases, 12 from scarlet fever, 10 from measles, 4 from diphtheria, 3 from enteric fever, and 2 from whooping-cough, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·9, against 1·3 and 1·6 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 19, 21, and 10 in the three preceding weeks, rose to 13 last week, and included 7 in Dublin and 2 each in Belfast and Waterford. The deaths referred to scarlet fever, which had been 12, 6, and 14 in the three preceding weeks, fell to 12 last week, of which 6 were recorded in Belfast and 4 in Waterford. The fatal cases of measles, which had been 7, 11, and 9 in the three preceding weeks, were 10 last week, and comprised 9 in Belfast and 1 in Cork. The 4 deaths attributed to diphtheria, of which 2 occurred in Cork, were double the average in the earlier weeks of the quarter. Of the 3 deaths referred to enteric fever 2 were registered in Dublin and 1 in Belfast; the 2 fatal cases of whooping-cough occurred in Belfast.

The deaths referred to diseases of the respiratory system, which had been 61, 86, and 67 in the three preceding weeks, rose to 85 in the week under notice. Of the 423 deaths from all causes, 128, or 30 per cent., occurred in public institutions, and 7 resulted from various forms of violence. The causes of 9, or 2·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion was equal to 1·1 per cent.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1914.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 14·0 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding months the rates were 7·8, 7·5, and 11·6 per 1000 respectively. The lowest rates last month were recorded in Chelsea, Hackney, Holborn, the City of London, and Wandsworth; and the highest rates in St. Pancras, Bethnal Green, Stepney, Deptford, and Woolwich. Scarlet fever was again much more prevalent than it had been in any previous month of this year; the greatest proportional prevalence of this disease was recorded in Hammersmith, St. Pancras, Stepney, Southwark, and Deptford. The Metropolitan Asylums Hospitals contained 4561 scarlet fever patients at the end of last month, against 3113, 3199, and 4157 at the end of the three preceding months; the weekly admissions averaged 618, against 410, 414, and 598 in the three preceding months. Diphtheria was also very much more prevalent than in any earlier month of the year; this disease was proportionally most prevalent last month in Hampstead, St. Marylebone, St. Pancras, Stepney, Deptford, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1042, 1030, and 1296 at the end of the three preceding months, had further risen to 1489 at the end of last month; the weekly admissions averaged 213, against 131, 128, and 188 in the three preceding months. Enteric fever was slightly less prevalent than in the previous month; the greatest proportional prevalence of this disease last month was recorded in Chelsea, the City of Westminster, Holborn, Shoreditch, and Greenwich. There were 65 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 36, 39, and 57 at the end of the three preceding months; the weekly admissions averaged 11, against 6, 7, and 11 in the three preceding months. Erysipelas was proportionally most prevalent in Shoreditch, Bethnal Green, Stepney, Southwark, Deptford, and Greenwich. The 34 cases of puerperal fever notified during the month included 7 in Camberwell and 4 each in Stepney and in Southwark. The 3 cases of cerebro-spinal meningitis belonged respectively to Chelsea, Shoreditch, and Stepney; and of the 7 cases of poliomyelitis 2 belonged to Stepney and 1 each to Islington, Finsbury, Shoreditch, Lambeth, and Camberwell.

The mortality statistics relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs. During the four weeks ending Oct. 31st the deaths of 4894 London residents were registered, equal to an annual rate of 14·1 per 1000; in the three preceding months the rates had been 11·3, 12·6, and 15·5 per 1000 respectively. The death-rates last month ranged from 9·3 in Stoke Newington, 10·0 in Hampstead, 10·4 in Wandsworth, 10·5 in Lewisham, 11·0 in Chelsea, and 11·9 in the City of London, to 15·6 in Battersea, 16·3 in St. Pancras, 16·9 in Bethnal Green, 19·2 in Finsbury, 19·6 in Shoreditch, and 21·0 in Southwark. The 4894 deaths from all causes included 97 from measles, 23 from scarlet fever, 83 from diphtheria, 38 from whooping-cough, 11 from enteric fever, and 334 from diarrhœa and enteritis among children under 2 years. The lowest death-rates from these infectious diseases were recorded in Kensington, Chelsea, Hampstead, Stoke Newington, Holborn, the City of London, Wandsworth, and Lewisham; and the highest rates in Fulham, Islington, Shoreditch, Bethnal Green, Poplar, and Southwark. The 97 fatal cases of measles were 26 above the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Hammersmith, St. Pancras, Hackney, Shoreditch, Bethnal Green, Poplar, and Southwark. The deaths from scarlet fever were 7 above the average; of the 23 fatal cases recorded last month 6 belonged to Stepney, 3 to Fulham, and 2 each to Islington, Bethnal Green, Poplar, and Wandsworth. The 83 deaths from diphtheria were 42 in excess of the corrected average number; this disease was proportionally most fatal in Fulham, Hampstead, Islington, Shoreditch, Camberwell, and Woolwich. The 38 fatal cases of whooping-cough were 3 above the average; the highest death-rates from this disease were recorded in Paddington, Fulham, Finsbury, Shoreditch, Bethnal Green, and Southwark. The 11 deaths from enteric fever were 11 below the average, and included 2 in Hampstead and 2 in Lambeth. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Shoreditch, Bethnal Green, Poplar, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was 36·2 per cent. above the average.

NATIONAL UNIVERSITY OF IRELAND.—Among those who have been coöpted Members of the Senate of the National University of Ireland are Dr. J. F. O'Carroll, of Dublin, and Mr. C. Y. Pearson, of Cork.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING OCTOBER, 1914.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1914.	NOTIFIED CASES OF INFECTIOUS DISEASE.												DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.									Deaths from all causes.	Death-rate per 1000 living.†
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total. Obituary.

ISAAC BURNEY YEO, M.D. LOND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL AND TO THE WESTMINSTER GENERAL DISPENSARY.

THE sudden death of Dr. Isaac Burney Yeo, of Cadogan-place, S.W., which occurred on Nov. 20th, removes a personality for many years familiar in the West-end of London and at many foreign health resorts.

Until comparatively recently Dr. Burney Yeo maintained such an appearance of youthful vigour that it will perhaps be a surprise to many to learn that he commenced his medical studies at King's College, London, so far back as 1858, and that even then his age was somewhat in advance of that of most of the men of his year. He gave early promise of subsequent distinction, being awarded one of the junior scholarships at the end of his first year, and later gaining the senior scholarship. In view of the trend of much of his work in after life it is interesting to note that in the first year of his studies he obtained a prize in materia medica. In 1865 he was appointed resident medical tutor at King's College, a post he held until 1871. Meanwhile he had been elected assistant physician at King's College Hospital, and was also similarly engaged at the Brompton Hospital for Consumption and Diseases of the Chest, a connexion which was continued for ten years. In 1871 he resigned the medical tutorship and took up his residence in Hertford-street, Mayfair, where he remained for the greater part of his life. Gifted with a fluent pen and a graceful style, he wrote many articles in the *Fortnightly*, the *Contemporary*, and the *Nineteenth Century* on subjects connected with the treatment of various forms of disease at foreign health resorts, and doubtless these contributed largely to his success in his particular line. In preparing for these articles he took long autumn holidays in Switzerland, and in the days when it was permissible to practise there without having a foreign qualification he used to astound medical climbers by always appearing dressed as though about to visit patients in town. Those who knew him well realised that it was impossible to expect to see him in loose, untidy garb; when in London he always affected the same trim appearance, and maintained a calm, deliberate professional manner. In 1885 he was made professor of clinical therapeutics at King's College, but the course of lectures was not obligatory and was poorly attended, though it led to the publication in 1893 of a very successful "Manual of Medical Treatment." In this work he approached the teaching of therapeutics from the side of the disease, and not from the side of the drug or remedy, following the example of Dujardin-Beaumetz in his "Leçons de Clinique Thérapeutique" and of Hare's "System of Practical Therapeutics," and freely acknowledging his indebtedness to these authors. From its lucidity this book met with ready acceptance and speedily passed through several editions. The other two books from his pen, "Food in Health and Disease" and "Climate and Health Resorts," although they possessed the same charm of diction, were addressed more to the public than to the student of medicine, and did not attract much attention. For a short time before the end of his career at King's College Hospital he was associated with the late Dr. A. B. Duffin as joint professor of medicine, and on his retirement he was elected consulting physician and emeritus professor of medicine.

As a teacher in the wards he was perhaps unduly emphatic and impressive; students, who are keen critics, were sometimes suspicious of a steady level of emphasis. His teaching was sound, however, and it was based on considerable experience of all chest diseases, while his ready store of knowledge of matters connected with climatic and therapeutic details was invaluable to those who were sufficiently advanced to appreciate the wealth of material presented to them. Still it must be confessed that many who heard of the advantages of the climatic treatment of consumption over the bedside of an ordinary patient in hospital were inclined to be sceptical, so long as these improvements could not be demonstrated in the case which furnished the text for the discourse. Of his sincerity there could be no question, but students, unless of the post-graduate type, desire a supply of material which can be of service in the examination room or of which they can expect to make use in the near future, among the poor patients likely to be their portion in the early years after qualification. While his teaching was, therefore, in advance of the needs of the average student, his house physicians and many young practitioners learnt to respect his obvious sincerity and to be grateful for innumerable hints which resulted from observation or from a watchful interest in current literature.

It is somewhat difficult to estimate his position as a colleague. Comparatively early in his career he was disappointed by the non-realisation of cherished schemes, and this led to a degree of angularity towards certain senior colleagues to whom, rightly or wrongly, he attributed the slight. This led to a certain aloofness which pervaded his relationship with many of his colleagues, and, while he was capable of forming many firm friendships, his attitude towards colleagues was frequently marked by an air of neutrality, and sometimes of hostility. To those who were admitted to intimacy he was at all times charming; as a raconteur, especially of gossip connected with professional matters, he was probably unrivalled, and as a member of the Garrick Club it was natural that many of his anecdotes should be connected with literary, artistic, and theatrical subjects, which never fail to find eager auditors. This facility always led to a ready welcome in society, and for many years his figure was familiar also at the meetings of the British Medical Association. On several occasions he contributed papers at these annual gatherings, but his sensitive character and his impatience of opposition led to some degree of friction on more than one occasion.

As a scientific physician he was distinctly successful in acquiring a high class of consulting work; his emphatic manner was impressive on medical points, while it was once remarked of him that on entering a drawing-room he instinctively knew the right amount of deference to be observed to each individual lady of title who might be present. The secret of his success, however, was more probably to be found in the diagnostic skill he brought to each patient and in his method of coping with the difficulties presented by each individual case. Reference has already been made to his range of professional study and his ready assimilation of new ideas. Among other examples may be instanced his development of the theory of intestinal antisepsis, his construction of the inhaler for consumptives which bears his name, and the evolution of a special form of treatment for typhoid fever. The number of new remedies he employed in hospital work can be gathered from a perusal of the early editions of his "Manual of Medical Treatment," but while he felt impelled to test the validity of every claim, his conclusions may frequently be summed up as "Non proven." Enthusiastic, yet cautious, bold and plain speaking, yet sensitive and reserved, filled with the self-respect which he considered was his due as a representative of an honourable branch of the medical profession, his sudden death creates a blank in the fast thinning ranks of general physicians.

Rather late in life he married Winifred Helen, daughter of the late Dr. T. Spyers, who survives him. He leaves no children.

EUSTACE SMITH, M.D. LOND., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN; CONSULTING PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

Dr. Eustace Smith, whose death occurred after a short illness on Saturday, Nov. 14th, in his eightieth year, was the third son of the Rev. J. H. Smith, vicar of Milverton, Warwickshire, and was educated first at Leamington College and afterwards at University College, London. He studied for some time in Paris, qualified M.R.C.S. Eng. in 1858, and subsequently graduated as Doctor of Medicine in the University of London in 1865. In 1870 he joined the staff of the East London Hospital for Children, Shadwell, becoming senior physician to that hospital as long ago as 1874, in which year he was elected a Fellow of the Royal College of Physicians of London. Despite his age he was in active consulting practice till a few weeks ago, and his keen interest in medical work in its relation to the health of the child was never relaxed. At the Seventeenth International Congress of Medicine held last year in London he was President of the Section for Children's Diseases, and he was a late president of the Medical Officers of Schools Association. For some time in his earlier professional career he travelled with the late King of the Belgians, Leopold II., by whom he was appointed physician, and nominated Chevalier of the Order of Leopold.

Dr. Eustace Smith was a frequent contributor to English and American medical journals, and was the author of a book entitled "Wasting Diseases of Infants and Children," which has gone through six editions, and thoroughly deserved its popularity. He wrote also "A Practical Treatise on Disease in Children," "Clinical Studies of Disease in Children," and "Some Common Remedies and their Use in Practice." He also contributed the article on "Diseases of Children" in Quain's "Dictionary of Medicine," and wrote many other articles on allied subjects for Allbutt's "System of Medicine," "The Index of Treatment," and Latham and English's "System of Treatment." He married in 1875 Katharine Isabella Place, by whom he had a son and a daughter.

Dr. Graham Little writes: "Dr. Eustace Smith's name is imperishably associated with the East London Hospital for Children, of which he became senior physician as long ago as 1874. As now the oldest member of the active staff of that hospital I should like to put on record some of the personal impressions left by 19 years of close association with him. Although he had joined the staff long before some of its present members were born, he retained to the very last—and I came home with him from the hospital only 12 days before his death—a vigorous openmindedness which the youngest of us might envy, and which accorded well with his singularly youthful appearance. He was delighted when, as often happened, patients who had consulted him some 20 or 30 years earlier, sought him out, and when confronted with him insisted that he must be his own son. 'When I was a child,' such a patient would say, 'I was taken to see your father,' and 'Sometimes,' said my old friend, 'I do not trouble to disabuse them by telling them that it was myself they saw.' It was our custom since I joined the staff to hold an annual dinner of past and present members, of which I had the organisation. He was, of course, the permanent president of these gatherings, and has not missed one of them in 19 years. Awaiting the arrival of guests at one of these functions, I was standing with Sir Bryan Donkin at the head of the stairs leading to the reception room. We saw a tall and agile figure bounding up from the foot of the long ascent, taking three steps at a time. 'That is certainly Smith,' said Donkin; 'no one else is as young as that,' and he was right. If Heckford originated the East London Hospital for Children, Eustace Smith made and established its present great reputation. He loved it like a father. Joining the staff only two years after its foundation, for 43 years he gave unstintingly of his time and thought and care. His management of committee meetings, both medical and lay, was delightful. I feel sure that there are many other members of the present staff who, like myself, have felt so strong an affection for 'our senior physician' that we have remained members longer than we should otherwise have done were it not for the lure of that commanding personality. He was ever ready to help his younger colleagues, whether it might be to put practice in the way of the struggling junior, to help a man to the coveted F.R.C.P. in the most unobtrusive and delicate manner, or to place at his disposal his marvellous store of experience. His spirit permeated the entire institution, and everyone who has ever been associated with 'Shadwell,' in any capacity whatever, loves it with a very special love. He had a very happy and humorous readiness of repartee. He used to narrate with glee a little incident which happened in his attendance on King Leopold of Belgium, whose physician he was up to the King's death. During one of his visits to England His Majesty complained of insomnia, which Eustace Smith treated perfectly successfully with a nightly dose of 15 grains of bicarbonate of soda. The King returned to his own country, and it was only after some considerable period of time that he again met his English physician. When he did so something like the following conversation ensued: 'Do you know, Dr. Eustace Smith, that I showed the prescription you gave me for sleeplessness to my Court physician, and he tells me that you ordered me *common* bicarbonate of soda?' 'But, if I remember right, your Majesty benefited by my treatment.' 'Oh, yes, it cured my insomnia, but bicarbonate of soda is such a very commonplace drug. My physician was quite surprised at your ordering it for me.' 'Ah, your Majesty, you will forgive me for reminding you that Naaman the Syrian also objected to the Jordan as too commonplace a stream for his use—until immersion in it cured his leprosy.' Surely a knockout reply! Eustace Smith was immensely pleased with the well-deserved compliment paid to him in his selection to preside over the Children's Section at the last International Congress. But there is reason to think that the fatigue, and especially the disturbance of his very regular habits entailed by the abounding hospitality of that festival, first impaired his marvellous vitality. It is a curious coincidence that another most beloved octogenarian of a similar abundant activity, Lord Roberts, died on the same day and very nearly at the same hour. It is not too much to say that to a very large circle of friends and patients something like the same void is made by the death of 'our senior physician' as is felt by the nation at large to result from the loss of the great soldier."

Correspondence.

"Audi alteram partem."

VOLUNTEER SURGEONS FOR FRENCH HOSPITALS.

To the Editor of THE LANCET.

SIR,—As one of the men who answered Dr. James Donelan's appeal for surgeons for the French hospitals, my experiences in France may be of interest.

Accompanied by a colleague, Mr. A. L. Home, who like myself was recommended from the London Committee of the Croix Rouge Française, I went to Paris on Oct. 7th. On application to the head office of the French Red Cross we were told that at the moment there were no vacancies for supernumerary surgeons at the advanced ambulances. A wire, however, had just come in asking urgently for two English surgeons to take charge of a hospital at Villeneuve-sur-Lot, some 75 miles east of Bordeaux. Though we would have preferred to go to the actual front, we felt that we could not refuse; and in any case we were informed that just then very large drafts of wounded men were being sent down to the more remote parts of France in order to keep the metropolitan area free.

Our passports and credentials, including letters from influential persons connected with our provincial hospital at home, were duly examined. These being deemed satisfactory we were furnished with vouchers to obtain railway facilities and with a sort of contract setting forth that in return for our services we should receive board and lodging free. This contract was embodied in a letter of introduction to the lady who had sent the telegram and who it was that had turned her chateau into a hospital.

Travelling *viâ* Bordeaux, on arriving at Villeneuve we found there were five hospitals containing 775 beds. Of these one was directly under the military authorities (200 beds) with a resident medical officer, Dr. Guy, who is an excellent X ray worker, one with 200 beds under the Société de Secours aux Blessés, and three others under l'Union des Femmes de France with 200, 75, and 70 beds respectively. The last four were served by elderly general practitioners resident in the district, and had each an efficient resident staff nurse and a body of Croix Rouge helpers more or less trained. It was to one of the smaller institutions which had been established solely at the expense of Madame Georges Leygues that we were specially recommended, though our services were demanded later at all the other hospitals except l'Hôpital Militaire.

We had a cordial welcome from our French *onfrères*, and started into work at once at Madame Leygues's Hospital. But having been asked by the doctor in charge to see some of the more serious cases at one of the other hospitals, and having arranged to do the necessary operations for these, we were informed by the lady president of l'Union des Femmes de France that in case of any mishap the military authorities would hold her responsible unless we were previously "militarisés." This necessary formality should have been carried out for us by the committee in Paris. However, to rectify the omission Madame Leygues lost no time in taking us to Bordeaux, and we were formally "militarisés" by M. Millerand, the Minister of War, who, regardless of professional etiquette, gave us in writing amusingly plenipotentiary powers! Needless to say we used these with discretion.

This our second visit to Bordeaux was made very interesting through the kindness of Dr. Bourgonnier, who showed us systematically over his large hospital containing 2000 beds. It is established in a large college for boys, and is as near perfection as any such military hospital can be. Bourgonnier has a genius for organisation and discipline, and from the admission room, with its admirable arrangements for cleansing and germ prevention, to the mortuary and pathological section, no detail has been forgotten. He has a staff of experts for each department—pathological, X ray, operations, record department, &c.—and he has laid contribution on all the available medical and surgical resources of Bordeaux. He showed us one block palisaded off with high railings and barbed wire where about 50 wounded Germans lay. All their wounds were serious, mostly compound comminuted fractures. It was touching to see his kindness to these men, whose crestfallen and depressed demeanour contrasted markedly with the cheeriness of the wounded French. Asked how many of the 2000 wounded (including many severe compound fractures) who had had to have amputation of arm or leg performed Bourgonnier answered "none." Tetanus was being treated by thorough antiseptic cleansing and dressing. Deaths in the hospital from any cause had been few: three Germans and no Frenchmen up to Oct. 13th. We were also shown over two other large hospitals at Bordeaux. At one the ether and iodine treatment recommended by Dr. Vernier, of Hyères, was being extensively employed for tetanus with apparently marked success.

I was told on good authority that in Bordeaux and the immediately surrounding district alone there were 40,000 wounded. This is, I believe, not exaggerated. At Agen, a small town of 21,000 inhabitants, there were, I know, 2000 wounded. This was included in the Toulouse district, which was very full early in October, but had, on the authority of the General commanding, 2000 empty beds by Nov. 1st. Immediately on our return to Villeneuve we installed an operating theatre, the room which had been allotted for that purpose in the largest of the Red Cross hospitals being unsuitable from a surgical standpoint. We were given a small but lofty ward with a good north light. This was thoroughly scrubbed and limewashed, and a wooden partition quickly run up, forming a useful ante-room. Marble-topped restaurant tables freshly enamelled served for operating-tables, and to hold basins, instrument trays, &c. A portable stove and sterilisers were quickly forthcoming. Money was no difficulty.

During the remainder of our stay we acted as consulting and operating surgeons. The practitioners gladly gave us every facility. With the greatest kindness and courtesy they turned the existing bad cases or any fresh severely wounded over to us, besides allowing us a general supervision over all the wards. As has been generally found everywhere, fresh bullet wounds healed quickly and kindly. Shrapnel frequently caused suppuration owing to the carrying in of fragments of clothing or to contamination from earth or clothes entering the ragged wounds. Among the cases we had under observation shrapnel and bullet wounds were in about equal proportion. It was not always easy to exactly tell what the projectile had been. We had no leg or arm amputations. Conservatism patiently and thoroughly carried out sufficed. Some finger amputations were necessary and extraction of irritating bullets. The careful dressing of large wounds, removal of sequestra, setting and thorough antiseptic dressing of compound fractures, scraping of sinuses and such like made up our operative work. We noted some extraordinary escapes. Two men were shot clean through the neck horizontally at the level of the upper border of the thyroid cartilage. Beyond the fact that one had had his recurrent laryngeal involved and was very hoarse, neither of them was a pin the worse. I had a case almost identical with the hand figured on p. 1174 of THE LANCET of Nov. 14th, except that the bullet entered the back of the hand and made an extensive wound of the palm. I considered that this was not due to a dum-dum but to the fact that the head and shaft of the second and third metacarpal bones were smashed and driven through the muscles and skin. It was suppurating profusely when I saw it first and causing intense pain. I removed several sequestra, thoroughly scraped it, swabbed it with iodine, and put the hand into a continuous boric bath. It healed well.

A word as to the nursing and feeding at these hospitals. It was excellent. Those southern women are extraordinarily adept. Though possessed of a comparatively meagre preliminary training, they had imbibed the aseptic idea, and their unofficious tenderness, natural skill, and charm of manner rendered them most suitable for the work they had to do. Their facility at massage was remarkable, and they faithfully carried out orders. Many of them were, of course, intelligent ladies, and they were not playing at nursing. The daily menus, and still more the appetising invalid cookery for special cases, were admirable. I consider the men were well nursed. The work of the general practitioners was most creditable and entirely voluntary, and once we had been properly accredited our help was unreservedly and gratefully sought by them.

We left at the end of our month as we had information that for the present no more fresh wounded were to be sent into that district. Any surgeon with some facility in French desiring to help in a capacity similar to that I have sketched and not expecting to get much major surgery should find a useful and helpful sphere—and incidentally a pleasant holiday—in France for months to come. There is a dearth of surgeons from causes already pointed out in your columns. Application should be made beforehand to the Croix Rouge Française, and all formalities should be strictly complied with so as to avoid vexation and delay. I am, Sir, yours faithfully,

Newport, Essex, Nov. 17th, 1914. J. ARTHUR BROWNE.

A PLEA FOR MORE CONSERVATIVE TREATMENT OF UTERINE APPENDAGES.

To the Editor of THE LANCET.

SIR,—One is impressed with the number of women nowadays who, for some reason or other, have been deprived of their reproductive organs, most of them for very weighty and necessary reasons. The modern gynæcologist has reduced the mortality of such operations to so small a percentage that it would seem that milder measures are often pushed aside as probably useless and tedious before they have been given a fair trial. These remarks, of course, apply chiefly to inflammatory conditions and the resulting adhesions. As illustrative of the class of case I have in my mind the following history is so unusual and instructive that I hope it justifies publication.

The patient, aged 33, had had three children, the first at full term and the second and third at seven months, all living. Six years ago her fourth pregnancy aborted at four months. There was considerable difficulty in extracting the fœtal head, and she had a sharp attack of pelvic inflammation in which the cellular tissue was largely involved. She was treated for some months by the usual methods, and an autogenous vaccine was also used over a long period. The infection was streptococcic. A purulent vaginal discharge, with occasional febrile attacks accompanied by pelvic pain, persisted, and early in 1911 she had an acute and definite attack of pyosalpingo-oöphoritis accompanied by a most profuse discharge. She recovered from this and tried a course of treatment at Ems. But at intervals she continued to have what may be termed "flares up," when the attacks were sufficient to cause considerable alarm.

Four consulting surgeons and gynæcologists of the highest reputation and standing expressed the opinion at various times that the patient would not be well until both tubes had been removed, and advised her to submit to the operation. A room at a nursing home was actually engaged and the date of the operation fixed, but as an example to all our British women in this present era she persisted that she meant to have as many children as it was possible, and that nothing would induce her to allow them to rob her of all such chances until absolutely compelled. Accordingly, her husband then took her to Paris and consulted Professor Pinard, who expressed his opinion to me that with absolute rest, long-continued hot douches, and rectal lavement she would get quite well, and added that he saw no reason why she should not become pregnant again. The former seemed possible, but the latter—considering the numerous repeated attacks of salpingitis, first in one tube, then in the other, and sometimes in both at once—seemed more than improbable. However, after two years' constant treatment she surprised everyone by becoming pregnant, and has now produced, with hardly any trouble from start to finish, a peculiarly healthy and fine infant at full term.

The patience and perseverance required would have been practically prohibitive to one of the working classes, but a history of this case may perhaps encourage greater patience on the part of some gynæcologists when treating any but the severest cases, and perseverance in treatment on the part of their patients when in a position to be treated for a sufficiently long period.

I am, Sir, yours faithfully,
Edward P. Furber, M.R.C.S. Eng.,

INTRATRACHEAL ANÆSTHESIA.

To the Editor of The Lancet.

Sir,—Mr. Wilfred Trotter's letter in your issue of Nov. 14th raises some points of interest to which I should like to reply. In the first place I find that he has no objection to the use of the intratracheal method in certain cases of cancer of the tongue—in fact, that he has often used it himself. This is an unexpected but welcome admission, unexpected because it was, I submit, impossible to infer this from his article, in which the intratracheal method was briefly mentioned and quickly condemned. Mr. Trotter objects to its use solely in cases in which the growth is foul and ulcerating. I should like to convince him of the safety of the method even in these cases. I have not unfortunately an accurate record of the nature of the growth in all the cases, 48, mentioned in my letter of Nov. 7th, but I find that at least 12 of them are noted as being large ulcerating growths. It is highly probable that some of the remaining 36 were not clean, although it must be stated at the same time that in several cases the growth was on the lip or anterior part of the tongue, and in consequence very unlikely to come into contact with the laryngoscope. I think the danger of bruising or tearing the growth is exaggerated. The anæsthetist can, if he is careful, avoid rough contact with the ulcerating surface.

In the second place I find it very difficult to agree with Mr. Trotter that the introduction of the tube is followed by spasmodic inspirations. It seems to me that he does not give due credit to the strong defensive reflexes of the larynx and trachea which (unless deep anæsthesia is present) are at once brought into play by the presence of the catheter so that coughing ensues, is made more vigorous by the addition of the ether vapour, and continues until deepening anæsthesia cuts it short. So strong are the respiratory efforts that the catheter may be forcibly coughed out—this happened to me on one occasion, the catheter being expelled a distance of at least four feet—and every writer describing the technique draws attention to the necessity of holding the catheter in place. If anæsthesia is deep on the introduction of the catheter there is, in my experience, no perceptible change in the character of the breathing, certainly nothing of the nature of spasmodic inspiration. The addition of the ether vapour may not in this case call the cough reflex into play, but it does immediately provide a strong upward draught at the glottis which would dislodge any septic material in the neighbourhood.

With regard to Mr. Rupert Jones's cases in The Lancet of Nov. 7th (p. 1087), I do not think we are justified, after reading Mr. Hey Groves's letter in your issue of last week (p. 1220), in coming to the conclusion adopted by Mr. Trotter as to the origin of the lung infection.

Lastly, may I say that it was tracheotomy to which I took the objection that it increased the length of operation, not laryngotomy? The complications and difficulties of tracheotomy are the province of the surgeon. I feel, however, that catheterization is a simpler and less harmful procedure than either, and I am not convinced of the danger which prevents Mr. Trotter from adopting intratracheal insufflation in all his cases.

I am, Sir, yours faithfully,
Francis E. Shipway.
Queen Anne-street, W., Nov. 23rd, 1914.

IMMEDIATE MASSAGE OF SEPTIC LIMBS.

To the Editor of The Lancet.

Sir,—The immense number of septic wounds being treated at the present time is my excuse for advocating in print a line of treatment which must be well known to the majority of the medical profession. In spite of the fact that the treatment of septic infection of limbs by immediate massage is an old one, many people object to it on the ground that it "spreads the toxin," but on being asked if they have tried it they almost always answer No. My own practice is to massage the limb the day after it has been freely incised and drained, the limb being taken out of the bath for massage. This treatment must, of course, be carried out by a skilled masseur.

I am, Sir, yours faithfully,
Malcolm Donaldson, F.R.C.S. Eng.
Le Havre, Nov. 20th, 1914.

THE 2nd LONDON CLEARING HOSPITAL.

To the Editor of The Lancet.

Sir,—I should be very grateful if you would let it be known through the columns of your journal that the 2nd London Clearing Hospital is now being mobilised for service with the British Expeditionary Force and requires the services of two highly competent operating surgeons to complete its surgical staff. The clearing hospital, situated a little distance behind the fighting line, receives all the wounded of a division and is equipped to deal at once with the most serious cases. The officers appointed will receive commissions in the Territorial Force for the duration of the war.

I am, Sir, yours faithfully,
Chas. Monk,
Lieutenant-Colonel, I.M.S. (retired),
Officer Commanding 2nd London Clearing Hospital.
Duke of York's Headquarters, Chelsea, S.W., Nov. 21st, 1914.

SANATORIUM TREATMENT.

To the Editor of The Lancet.

Sir,—The comments of Professor Bang which you mention in The Lancet of Nov. 14th, p. 1159, on the results of sanatorium treatment are to my mind somewhat extraordinary. In the first place, I should like to mention that out of 800 cases received into this sanatorium no case which was definitely unable to work on discharge has recovered after going home; it is true that two cases have improved temporarily beyond all expectation. With regard to first-stage cases not doing so well as many more advanced cases the reply is obvious. It is seldom that a first-stage case is admitted to a sanatorium unless suffering from severe or fairly severe general symptoms; all the mild cases are treated at home and made into chronics, who may live for years in imperfect health, often capable of much improvement with a little rest. When the profession learns the proper way to treat an early case of phthisis with slight symptoms we may hope to get rid of the large number of chronics who are constantly about infecting the population.

The proper and best use of sanatoriums for the working class, at least, is to use them for the treatment of cases as early as possible, and they should not be allowed to work until either they have become favourable chronics or unfavourable acutes. It is more than probable that there is something radically wrong with the treatment at sanatoriums where so many have to return home before they even partially recover. The recovery of first stage cases without manifestly acute symptoms is usually uneventful, so much so that no belief in the existence of the disease remains at the end. An exception should be made with reference to children who usually require great patience to cure.

I am, Sir, yours faithfully,

EDWARD E. PREST.

Ayrshire Sanatorium, Nov. 17th, 1914.

PATRIOTISM OR ADVERTISEMENT?

To the Editor of THE LANCET.

SIR,—I presume that many members of our profession, like myself, have had sent to them a tin box for the collection of subscriptions in aid of the National Relief Fund. Upon this box or canister is an advertisement of a food for infants. It seems impossible to regard this otherwise than as a peculiarly ill-timed method of advertisement, and I hope members of our profession will resent it in an appropriate and practical fashion.

The box which was sent to me is on my consulting-room table, but the names of the advertisers and their wares have been carefully removed.

I am, Sir, yours faithfully,

HERBERT TILLEY, F.R.C.S. Eng.

Harley-street, W., Nov. 23rd, 1914.

THE WILD GIRL OF NAINI TAL.

To the Editor of THE LANCET.

SIR,—The story in the *Pioneer* to which reference has been made in THE LANCET was a gross exaggeration. The correct facts are these. An imbecile girl, aged about 10 years, was found strayed, and brought in by the police to the Crosthwaite Hospital. She was a very ordinary imbecile and showed no more signs of neglect than many other similar unfortunates. Her nails were not a quarter of an inch long, her hair was short and not matted, she ate ordinary food in the ordinary way when it was given her, she understood similar orders like "Sit down!" "Come here!" and even obeyed the ordinary Hindustani signs of beckoning. She had no unusual growth of hair, and though naturally enough was frightened in her new surroundings for the first day or so, there never was anything about her suggesting the wild human.

As I have said, she was a very ordinary imbecile, and has been sent to the lunatic asylum at Bareilly. I am, Sir, yours faithfully,

Naini Tal, U.P., India,
Oct. 9th, 1914.

T. HUNTER,
Major, Indian Medical Service.

THE WAR.

THE MENACE OF CHOLERA.

PERHAPS the most important item of medical war news during the past week or two has been the intelligence that cholera has appeared in various parts of Austria and Hungary. The authorities apparently succeeded in keeping the matter secret so long as it was confined to Galicia and Moravia: but it has now appeared in various parts of the dual empire, some hundreds of cases being reported in Vienna itself. This scourge always enters Europe from the East, and though the onset of winter is against its rapid propagation, the conditions of war now prevalent on the borders of Russia, Germany, and Austria undoubtedly render its rapid transmission westward a danger in the situation to be seriously considered and guarded against.

THE HEIGHT STANDARD AND RECRUITING.

A reduction in the minimum height of recruits has often been advocated. Under ordinary circumstances in our army the physical measurements required are increased or relaxed in stringency according to the supply of recruits available. Rajah Brooke of Sarawak wrote a few days ago urging that shorter men ought not to be excluded from defending their country: "They are assuredly not to be despised; they are more nimble than their higher brothers, and as for bravery no man can think they are wanting." The regulation requirements of 5 ft. 3 in. in height and 31 in. chest measurement can hardly be considered too stringent, especially as they may be relaxed in special cases at the discretion of the recruiting inspector. In the new bodies of troops raised for special service the precise measurements have not been insisted on, any man physically fit being accepted, and the age limit being extended to 38 years. We believe that the response to the call for men has been on the whole satisfactory up to the present, but there must be no slacking off. More men are still required to fill up the places in the front. The supply must be continuous, not a mere "dribble of reinforcements," but a steady influx of fresh troops to take the place of, and give much needed rest to, those who have been bearing the brunt of many weeks' hard fighting.

THE CASUALTY LIST.

The following casualties among officers of the Royal Army Medical Corps have been officially reported since our last issue:—

Killed: Captain Cecil Taylour Conyngham (in East Africa).

Wounded: Major A. W. A. Irwin, Captain C. J. Coppinger, and Lieutenant A. Watson. Lieutenant W. H. Lister is unofficially reported wounded.

COMFORTS FOR THE ROYAL ARMY MEDICAL CORPS.

There are now some 10,000 men of the Royal Army Medical Corps at the front, and a committee has been formed, with Lady Sloggett, wife of the Director-General with the Expeditionary Forces, as its president, for the purpose of sending "comforts" direct to the commanding officers for distribution. The committee will gratefully receive, pack, and forward such articles as cigarettes, tobacco, and woollen goods, which are urgently needed. Parcels should be addressed, carriage paid, to "R.A.M.C. Comforts," Royal Army Medical College, Grosvenor-road, London, S.W.; and gifts of money should be sent to the secretary of the Royal Army Medical Corps Fund, Lieutenant-Colonel F. W. H. Davie Harris, 124, Victoria-street, S.W. We cordially associate ourselves with the objects of Lady Sloggett's committee.

THE WOUNDED AT CALAIS AND DUNKIRK.

Our Special Sanitary Commissioner sends the following notes in continuation of those which we published from him last week. We would remind our readers that the wounded to whom he refers are not British soldiers, but principally those of our Belgian allies:—

Complaints have been made concerning the condition of the trains used for carrying the wounded. Certainly where such emergency arises that cattle-trucks, commercial vans, or cars constructed for the transit of merchandise have to be converted into ambulance wagons much hardship and discomfort ensue. The wounded remain on the stretchers that bore them from the field, and 12 such stretchers may be in one cattle-truck. Of course, also, there is no corridor by which intercommunication can be established between these trucks, and any attendants who accompany the train cannot go to and fro among the patients. The journeys are often very long and no proper sanitary conveniences can be supplied. Though there are thousands of willing hands in all the towns who would gladly bring food and whatever may be required to the stations where the trains stop, it is not always known when the wounded are coming. The state of things is rapidly improving, but there was a great deal of misery in many places before better organisation prevailed.

There are a number of specially constructed corridor ambulance trains now operating in Northern France in which the wounded can be properly nursed and fed during the journey. But it is not always possible to bring these trains up to the point at which they are wanted, and this at the right moment. Then it has happened too often that the number of wounded is much in excess of the proper accommodation available, when it becomes necessary to adopt any expedient so as to bring the wounded where they can be properly treated. I saw two ambulance trains and they were both corridor trains, and if in respect of the brightness and cleanliness that distinguish a well-kept hospital much was wanting, they were at any rate doing extremely valuable service.

The Cleaning of Ambulance Trains.

Whether it was the carnage of war or the prevalent talk of German Kultur, I do not know, but a picture of what the Germans really do well came to my mind. The supervision exercised over the cattle trains at the Berlin municipal abattoir recurred to my memory. For these trains there is a convex cemented flooring with gullies leading to drains at short intervals along the track, so that the dirt washed out of the trucks should not sink into and contaminate the subsoil. There is regular cleaning out of the trucks at these intervals. Big reservoirs, built high, give a good head or force to water delivered by a hose. A regular staff, with buckets containing a 5 per cent. hot solution of soda, scrubbed, mopped, and squeegeed the inside of every cattle van. This was done after every journey, and all the year round, irrespectively of the prevalence or otherwise of any sort of cattle disease. At this stage I do not wish to criticise the conditions of ambulance trains, nor do I for a moment mean that an ambulance train should or could be treated like a cattle train; but what can be done for cattle should be greatly improved upon when it is a question of men, especially of wounded men. In all the towns where ambulance trains stop there are numerous unemployed who for this reason or that are not with the colours. Work might be found for some of these in dusting, cleansing, washing, and disinfecting the ambulance trains, and as this war settles more and more into a tedious affair of trench fighting, horribly relieved now and again by furious local assaults, some such organisation will doubtless be evolved.

The Need of Scavenger Brigades.

Nor is this the only work that such a cleansing brigade would have to do. When they arrive at the end of their journey the wounded cannot, as a rule, be taken from the train to the hospital, or it may be the ship, that is to receive them. They have to be classified, and usually their wounds need fresh dressing. In earlier days they were put in the station waiting-rooms or laid on the platforms; but now at Calais, at Dunkirk, at other stations where I have been, and, doubtless, at many stations where I have not been, sheds formerly used for the storing of goods have been converted into depôts for the wounded. Here, at least, they are under shelter and can receive some attention. Then according to the accommodation available and the nature of each case the patients are placed in the ambulance motors or carriages waiting outside and driven to a ship or a hospital. But these sheds were not built as hospital wards, and they require a great deal of scrubbing and cleansing to make them suitable for the purpose. Thus a cleansing brigade might be very usefully employed here as well as in the trains. Besides, we must always contemplate the possibility of some serious epidemic following in the wake of war, though the freedom of the allied forces from this scourge has so far been remarkable—or, perhaps, it would be more just to describe it as the proper return for extraordinary prevision and scientific labour. Therefore, the drilling of a sufficient number of men to be efficient cleansers and disinfectors is a very necessary precaution. Indeed, so far as my Dunkirk and Calais experience goes, I did not hear any demand for additional surgeons, only for a few more consultants. Some extra-trained nurses and dressers would be welcome; but the need, the great, urgent, crying need, was, it seemed to me, for scavengers and people to brush and to scrub. For this is a dirty war. The menial work is that which is most needed.

Railway Sheds as Depôts for the Wounded.

At the request of the Wounded Allies Relief Committee I drew up a report on the condition of the Dunkirk railway sheds where the wounded are received. The committee at its last meeting considered it advisable to withhold this report from publication, at least for the present—and I was not surprised. Moreover, some improvements had already taken place before it was presented. Some beds had been provided where formerly there was only straw, and straw that was not changed too often. Nor was the attention given to the wounded in earlier days as prompt as it should have been. This now is improved, but still needs improvement. There is, however, every reason to hope that, when proper representations have been made to the authorities concerned, the necessary measures will be taken. In the meanwhile everyone is anxious not to offend justifiable susceptibilities. This is the more necessary as the position is very complicated. Of course, being within 20 miles of the German trenches and a French town, the French military authority is the supreme authority in Dunkirk. On the other hand, Dunkirk is within five miles of the Belgian frontier and that small corner of the little kingdom where what remains of the heroic Belgian army is defending its native land with flood, fire, and sword. Therefore, a portion of the Dunkirk town hall has been assigned to the Belgian Minister of War, who is also the Prime Minister. From here the Baron de Broqueville directs and sees to the needs of the Belgian army. With a motor he can reach the advanced posts in less than an hour. On the other hand, all those who have a short release from duty in and near the fighting line in Belgium come into Dunkirk to recuperate, to enjoy a good meal and some rest. Thus though this is a French town, the scenes around are such as to give the place a Belgian appearance. So far as the British contingent is concerned, Dunkirk is a naval rather than a military post. Thus, what with the French military command, the British naval command, and the Belgian Premier and Minister of War, all exercising authority, the desire to obtain a scrubbing brush or a little carbolic acid may assume the intricate aspect of a complicated international diplomatic and military problem.

British Volunteer Hospitals.

Fortunately there is a levelling and an assimilating effect produced by war which wears down rough corners. Differences disappear in the face of results. The Society of Friends, Millicent Duchess of Sutherland, and others have stepped into the breach, and now there are hospitals, admirably situated on the seashore, where French, British, Belgian, and German soldiers receive every attention from skilled English surgeons and highly-trained English nurses. All this seems to be in defiance of order and regularity, but in practice it works well, for it has largely contributed to save life and mitigate the terrible sufferings of the wounded.

British Help.

Further, this is a good example of the position in which the British nation stands in regard to the care of the wounded. There is no fighting in England, but there are any number of trained nurses and medical men who are most anxious to give their services. Some of them have gone over to France or to Belgium in the hope of being able to do something, but in war time the isolated individual is always looked upon with suspicion; therefore these volunteers had better strive to work for and through the well-known and accredited institutions. On the other hand, these latter should open the gate wide to willing and competent helpers. The French, on their side, must not take it amiss if we occasionally offer to do some of their work for them—and that work would have been infinitely more valuable if a percentage of educated Englishmen could speak intelligible French, and understand it when spoken. Our allies must just take us as we are and let us help—it may be in a somewhat irregular but none the less effective manner. Their task has been so gigantic that it is no stricture on them to say that certain things have been wanting here and there. So far as this has been the case with regard to the wounded, there is voluntary help forthcoming in Great Britain eager to go to the front. We can send surgeons and nurses out of all proportion to the number of British troops at the front. There are wealthy persons in each division of the United Kingdom eager to do something, willing to provide motor-cars, surgical instruments, and even salaries so that trained nurses can go to the continent and not be obliged to ask for payment from those whom they serve. This our allies should look upon as our further attempt to come to their aid without hesitation or stint. "We no not wish to be officious, we do not wish to interfere; but our hearts bleed and we do want to help." I quote these simple words, uttered to me, because they so exactly represent the situation.

THREE MONTHS' STAY IN DRESDEN.

The following communication has been received by us from an English pathologist who was constrained to remain in Dresden during the earlier part of the war:—

At the outbreak of war on July 25th between Austria-Hungary and Serbia the writer was in Vienna. During the following week I was allowed to attend the hospital practice at the Van Noorden Institute, and during this time was treated with every possible courtesy. At the end of the week the work of the hospital had been so curtailed as a result of numerous absentees that it served no good purpose to remain in Vienna, and in the last express train (as I understood) I travelled to Dresden during the night of August 2nd with the intention of reaching England. On the following day, after visiting Friedrichstadtkrankenhaus in Dresden, where I had previously been working for a period of six months, I was asked to assist in the pathological department, as the assistant staff had with two exceptions left to join their several regiments. However, as during the day it had been decided by the local authority to allow no foreigner to enter the hospital, I was relieved of an awkward situation, and decided to continue the journey to England. It may be here remarked that the general opinion was, as far as could be judged from the newspapers, that England would probably not join in the war. Unfortunately, being arrested as a suspicious person on the evening of the 3rd and being set free through the good offices of the professor under whom I had been working, I missed the last train to England that day. I got out of Dresden on the night of Tuesday, August 4th, and having some knowledge of the German tongue, I was able to avoid declaring my nationality to the numerous passengers who were travelling in the military trains to their various destinations. At Hanover on Wednesday afternoon, August 5th, an examination of tickets and passports led to a detention of some eight hours in company with several Russian peasants. The officer in command of the watch was cautious, and in conjunction with his men pointed out the iniquity of declaring war on cousins and co-religionists—i.e., Protestants. My passport and tickets were taken away, and permission to seek out a hotel for the night was given, with a strong recommendation not to declare my nationality, or a bed would certainly be refused, and that, as the people were very bitter against England, I might be molested. A soldier of the watch very knidly offered to find me a hotel and to guarantee me protection. The proprietor of the hotel, after having declared his views on England's treachery, introduced me to his relations, some of whom in uniform were about to leave for the front. A Landwehrmann present assured me that he had then no personal grudge against me, but he would give himself the pleasure of introducing his bayonet to me if we perchance met later in Belgium. Not accepting the offer to work at the getting in of the harvest, I was allowed at my own request to return to Dresden on the following day in the company of reservists and German refugees from Belgium. Being more than once told I looked English, the fact without a direct denial passed unchallenged, and having mentioned that I studied medicine, mutual confidence was established after a discussion as to the best methods of treatment for the three cases of gleet amongst my companions.

For the remainder of the next three months I made an enforced stay in Dresden, but I was put to no more inconvenience than that caused by having to report myself twice weekly to the police authorities and to remain within the city boundaries. The definition of the city boundaries was seemingly elastic, and if inadvertently the limits were passed there was in Dresden apparently no resulting punishment. Throughout the police authorities were uniformly courteous. After Sept. 2nd I was even allowed to take photographs, with the exception of public buildings or railway works.

Through the German papers we in Dresden obtained rather a sorry view of the British nation. Articles appeared regularly to indicate the extent of our guilt in declaring war on Germany, numerous examples of political hypocrisy in our present and past national history were given, and our envy of Germany's commercial prosperity was said to underlie all the measures taken. South Africa, we were informed, had risen to throw off the British yoke, and the Mohammedan population of India and Egypt were about to utilise their opportunities to obtain their freedom. Recruiting, we learned, was slow in England, despite the large monetary offers to those willing to enlist. Public opinion against the British was influenced largely by two factors: the alleged employment of dum-dum bullets by the English and French and accounts of "inhuman" treatment of the civil German prisoners. An example from the Berlin *Lokal-Anzeiger* of Sept. 10th may be quoted: "Cartridges bearing the stamp Art. Dept. Ive. were found. The cartridges are therefore of English manufacture. Unabbreviated it would read: Artillery Depôt Ive (the corresponding French description would be: Dépôt d'Artillerie Ive). There is a small town Ive in the county of Cornwall (St. Ives was probably meant). The presence of an artillery depôt there was previously unknown to us. ......"

Quoting from the *Hamburger Fremdenblatt* of Oct. 26th and describing the conditions at Newbury: "Eight to ten Germans lay in a horse-box in old straw. Each man received two thin blankets, nothing more. At 5 o'clock in the afternoon everyone had to crawl into the straw. The prisoners must cook their own food. ...... A watery soup with the addition of a small amount of fat contained perhaps for each prisoner 1 cubic inch meat. The amount of nourishment was altogether inadequate. Anyone complaining was given three days on water and bread. ......" At the outbreak of war the enthusiasm for war was apparently intense, and at the beginning of November showed no signs of waning. The significance of the retreat from Paris was obscured by the obvious progress in Belgium and in Poland. From time to time detailed accounts of atrocities, judicially investigated, at the hands of the Russians, French, and Belgians, were published. After the British retreat from Mons there was in the press a general tendency to despise the British soldier, but in the latter months it was frequently mentioned that our infantryman was clever at entrenching himself, that he continued to shoot accurately whatever was occurring around him, and that he was exceedingly difficult to dislodge once he had taken up any position.

It will be gathered from our correspondent's letter that he had an anxious and sometimes a very painful time, but that on the whole he was very well treated. His great asset was, of course, his knowledge of German.

THE BRITISH RED CROSS SOCIETY.—The summary of the work for the week ending Nov. 24th states that the number of hospitals accepted by the War Office to date is 474, containing beds for 14,061, including 1312 beds accepted during the past week, and distributed among the Army Commands as follows: London, 818; Southern, 4355; Aldershot, 787; Eastern, 3657; Northern, 2336; Western, 1901; Irish, 207. A number of Red Cross Voluntary Aid Detachments are being utilised in connexion with these hospitals.

At the Netley Red Cross Hospital, which is being gradually extended, a large number of huts have now been opened. The dining hall for patients, erected through the donation given by Mr. Augustus Langham Christie, is now complete, and is a fine commodious building. The medical officers have moved into their huts, and one hut has been arranged in cubicles as a ward for sick officers. Owing to an urgent message from the War Office for as much accommodation as possible for Indian sick and wounded, two extra huts have been opened and the recreation room has been equipped temporarily for 50 patients, thus giving accommodation for 130 patients who arrive this week; 360 beds are now available. Two members of a women's Voluntary Aid Detachment are now doing duty in the Hampshire hut.

Motor ambulances have been coming in. During the week past 12 motor ambulances and 3 lorries have been shipped to Boulogne, while 50 motor ambulances have been sent to Newmarket and handed over to the officer commanding, Royal Army Medical Corps.

Nurses have been regularly detailed for duty. One nurse was posted for duty at Boulogne on Nov. 23rd. Twenty nurses were also detailed for duty in the following Home Military Auxiliary Red Cross Hospitals: Nov. 18th: Milton Hill, 2; Swanage, 2; Reigate (Ward), 1; Newbury (Lady Rosemary Portal) Hospital, 2. Nov. 19th: Louth, 1; Mayfield, Sussex, 1; Emsworth, 2. Nov. 20th: Kineton (Lady Willoughby de Broke), 1; Whitchurch (Lady Portal), 1. Nov. 21st: Spondon, 1: Hayling Island, 1; Whitchurch, 1; Duffield, 1; Gerrards Cross, 1. Nov. 23rd: Louth, 1. Nov. 24th: Thane, 1.

Sir Frederick Treves and Sir Rowland Bailey have at considerable length examined the plans of the Waterloo Hospital in association with the architect of the Office of Works. It will be staffed by 25 surgeons and 8 physicians chosen from the leaders of the profession in London who are available. The commandant and matron will be chosen by the War Office. Queen Alexandra and the Princess Victoria have made gifts of money for the equipment of beds, in addition to which 171 beds have already been endowed, His Majesty the King providing four. Each ward will contain about 360 beds and will be a complete hospital in itself, with its own operating theatre and surgical dressing room.

PROFESSIONAL CLASSES WAR RELIEF COUNCIL: MATERNITY NURSING HOME.—The Maternity Nursing Home for Wives of Professional Men, in connexion with the Professional Classes War Relief Council, to which we have already alluded in these columns, is now ready to receive patients. The home is primarily intended for the wives of professional men who are hard hit by the war, special preference being given to those recommended by the husband's professional society or institution. Wives of officers now serving are also eligible to be received. A small weekly charge is made to patients which is inclusive of all expenses. The voluntary medical staff and house committee include Sir Francis H. Champneys, Dr. Mary Scharlieb, Dr. H. J. F. Simson, Dr. Maud Chadburn, Dr. Florence Willey, and Dr. C. Gould May, and patients may also be attended by their own doctor, provided that his services are also rendered free of charge. The home is situated in No. 14, Prince's-gate, S.W., the beautiful house lent by Mr. G. Pierpont Morgan for the purpose, and contains every comfort and opportunity for good nursing. Wide publicity is required in order to insure the successful establishment of this home, and medical practitioners are asked to assist by making its existence known to those needing this type of help. Full particulars can be had on application to Mrs. Chambers, Maternity Nursing Home, 14, Prince's-gate, S.W.

CHLOROFORM IN FRANCE.—We called attention in THE LANCET for Nov. 7th to an alleged shortage of chloroform in the French war hospitals in various localities. Colonel F. N. Maude, C.B., and Vice-Admiral D. M. Riddell have now published a joint letter in the press positively asserting that such is the case, and asking for donations to a fund to enable an emergency anæsthetic centre to be established immediately, so that anæsthetics can at once be dispatched to hospitals in need. Donations, large or small, should be sent to Mrs. William Sharp, 49, Cambridge-street, Hyde Park, W., honorary secretary, or to Mrs. D. M. Riddell, 15, Mount-street, Grosvenor-square, W., honorary treasurer of the fund.—Lady Bagot, R.R.C., honorary secretary of the Church Army war hospital, who is working amongst the wounded at Dunkirk, reports that the shortage of nurses and the lack of chloroform there have rendered the situation one of sore necessity. In response to her urgent representations the Church Army have sent a large consignment of chloroform.

SUSSEX AND THE WOUNDED.—A local correspondent writes:—"Sussex is worthily fulfilling its part in succouring the wounded soldiers, both British and Belgian. In addition to having in its midst the Second Eastern General Hospital at Brighton, the other hospitals in that town and in all parts of the county have so generously offered their help that to enumerate them would be simply to give a catalogue of the various institutions. The Second Eastern General Hospital at Brighton is a collecting centre for the wounded. At one time early in November the whole of the 600 beds forming this hospital, including the annexe at the council school near by, were occupied. Private hospitality in the county has also been great, and patients have been distributed in all directions. In Hove a large private house has been lent for the purposes of a hospital by Mr. d'Avigdor Goldsmid, J.P., and the expense of fully equipping it for the reception of 20 officers and men has been borne by Mrs. Barney Barnato. No expense has been spared and the War Office readily accepted the gift. The medical staff comprise Major W. A. Bowring, consulting physician, Dr. E Hargrave Booth, and Mr. G. D. Kerr, while the matron is Miss Napier Ford, daughter of the late Dr. Alfred Napier Ford."

RED CROSS HOSPITAL FOR DUBLIN.—The scheme for the temporary enlargement of the several Dublin hospitals to accommodate wounded soldiers has been abandoned on account of the impossibility of all the hospitals joining. In the alternative the city of Dublin branch of the British Red Cross Society has decided to proceed with a scheme for building temporary additions to the existing King George V. Military Hospital. An appeal has been issued for funds for this purpose. The intention is to erect a number of pavilions, not exceeding ten in all, each capable of holding 50 beds. The approximate cost of each pavilion will be £1000, and the number to be erected will depend on the response to the appeal. As each pavilion is completed it will be handed over to the military authorities.

THE WOUNDED AT PORTSMOUTH.—Our correspondent writes: "It has been found necessary to increase the accommodation of the Fifth Southern Territorial Hospital. Accordingly, two wards in the Royal Portsmouth Hospital, each with 30 beds, and wards at the Portsmouth union infirmary with 80 beds, have been handed over to the military authorities. The Territorial staff attend to these patients. At the latter hospital most of the cases are surgical and came straight from the front, the dressings having been changed at the field dressing stations and at Calais. There have been two cases of tetanus—one fatal—both after severe shrapnel wounds. Three private houses, providing about 100 beds, have been generously placed at the disposal of the Red Cross authorities for the use of convalescents and cases of minor injuries among our soldiers and allies. Many have been sent from the Alexandra Military Hospital at

Cosham. The medical men and nurses give their services voluntarily, and so also do the orderlies and cooks. The Government make a small grant per soldier per day, which is insufficient to meet the necessary expenses. There are at present representatives of five different nations in Netley Hospital—British, Indians, French, Belgians, and Germans. This is the first time in the history of the hospital that such a thing has happened."

THE WOUNDED SOLDIERS IN BELFAST.—"Of the 58 wounded soldiers who came to the Royal Victoria Hospital," writes our Belfast correspondent, "21 have left convalescent, and of the 30 who were located in the Military Barracks a good number have also left. At the Royal Victoria Hospital, in the discharges from the wounds no anaerobic organisms have been found (as might be expected from the interval that elapsed between the infliction of the injuries and the arrival of the wounded at the hospital), but streptococci of a peculiar strain have been isolated. The committee of the King Edward VII. Memorial (which is to take the form of a block at the Royal Victoria Hospital for X ray and vaccine therapy) have made a special grant to commence work in the pathological department of the hospital, until the new building is completed."

THE students of the Schools of Surgery of the Royal College of Surgeons in Ireland are sending cigarettes, &c., to the students, Licentiates, and Fellows of the College at present serving with His Majesty's Navy and Expeditionary Forces. In order that none of the "old boys" shall be forgotten readers are asked to send names to the Registrar of the College.

2ND (RESERVE) LONDON SANITARY COMPANY.—An additional Reserve Company is being raised for the 2nd London Sanitary Company, R.A.M.C.(T.), and there are a few vacancies for officers. It is essential that officers be medical men with Public Health qualifications. All applications should at once be made to Captain C. M. Fegen, who is now raising this new company at the Duke of York's Headquarters, Chelsea, S.W.

Lieutenant-Colonel A. G. Hamilton, R.A.M.C. (T.F.), Officer Commanding Welsh Border Mounted Brigade Field Ambulance, Drill Hall, Bungay, East Suffolk, writes to say that he will be glad to hear from any medical man wishing to obtain a commission in the Royal Army Medical Corps (Territorial Force). There are several vacancies in the Imperial Service Unit now stationed at Bungay and in the Reserve Unit at Chester. Men joining for the period of the war only obtain an allowance of £20 for outfit, and those joining as Territorial officers for four years receive £40. In both cases a grant of £7 10*s.* is made for the purchase of camp kit. Pay and allowances are as in the Regulars.

EAST ANGLIAN PRACTITIONERS' MOTOR AMBULANCE.—Dr. Arthur Greene and Dr. J. T. C. Nash issued last month an appeal to their colleagues in the counties of Norfolk, Suffolk, and Cambridge, and the Isle of Ely for funds for the provision of a motor ambulance. A generous response has been obtained, and the total amount subscribed up to the middle of last week was upwards of £300, while many of the donors have promised to increase their contributions if necessary. The subscription list will remain open until the end of this month for any other medical practitioner who may wish to contribute.

VEGETABLES FOR SOLDIERS AND SAILORS.—An excellent movement has been started for supplying the men with antiscorbutic food. A Vegetable Products Committee has been formed, with Lord Charles Beresford as president, for the purpose of collecting and delivering fresh fruit and vegetables, jams, preserves, &c., and supplying them to army camps and stations, to warships and hospitals. 2000 cases have already been despatched to the North Sea, and with increased support the work might be much extended.

MOTOR-CARS FOR THE FRENCH RED CROSS.—The aim of the British Ambulance Committee to the French Red Cross, whose headquarters are Wimborne House, Arlington-street, Piccadilly, W., kindly lent by Lady Wimborne, is to make up the deficiency in the number of motor-cars available for ambulance work in France. In this way it is hoped to obviate the delay in transport from the front, which has resulted in much suffering to the wounded of our gallant ally and to save many who would otherwise perish. As a result of the appeal mentioned in THE LANCET of Nov. 14th £15,000 were subscribed within a week, while motor-cars and contributions continue to be received.

FISHMONGERS' HALL HOSPITAL.—In addition to the temporary hospital for officers which has been so admirably equipped at Fishmongers' Hall, the City branch of the British Red Cross Society proposes to establish another hospital of 100 beds in a large building close at hand, in Upper Thames-street, which has been placed at its disposal by the Pearl Assurance Company. In the brief account of the opening of the hospital at Fishmongers' Hall in THE LANCET of Oct. 17th it should have been stated that the honorary visiting physician in charge of the medical cases is Dr. Arthur T. Davies, senior physician to the Royal Hospital for Diseases of the Chest.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE General Council of Medical Education and Registration began its winter session at its offices, 299, Oxford-street, W., on Tuesday, Nov. 24th. The President, Sir DONALD MACALISTER, was in the chair.

New Member.

Dr. E. MAGENNIS took his seat as representative of the Apothecaries' Hall of Ireland for one year from August 1st, 1914. He was introduced by Sir Lambert Ormsby.

President's Address.

Sir DONALD MACALISTER then delivered the presidential address, beginning by pointing out that the Council was meeting for the hundredth session, but that there was no temptation to improve the occasion by reflections on the Council's past history when new history was in the making day by day. He made reference to the death of Sir Christopher Nixon and to the retirement from the Council of Dr. Adye-Curran and the election in the place of the latter of Dr. E. Magennis, Governor of the Apothecaries' Hall of Ireland. He alluded also to the absence of the General Registrar, Mr. Norman King, due to the fact that, holding the rank of major in the London Rifle Brigade, he had volunteered for foreign service. Mr. A. J. Cockington had been appointed, he said, Acting Registrar, and had discharged the duties to the complete satisfaction of the President and the Treasurers. Sir Donald reported the postponement of the new edition of the British Pharmacopœia, and of the regular inspection and visitation of the qualifying examinations, it being foreseen that during the next year occasion will arise for holding special examinations at other than the usual times. Dealing with this point he continued :—

Communications were received from several professional authorities inquiring as to the propriety of modifying or suspending some of the existing regulations in the case of students whose regular course of study for a medical qualification might be interrupted by reason of military service. The Executive Committee thought it right to intimate, by means of a circular addressed to all the licensing bodies, the answer it gave in the name of the Council to the general question thus raised. In view of its importance to the public and to the profession I think it well to repeat here the words of the answer :—

"With regard to the courses of study and examination prescribed for professional qualifications, it is the statutory duty of the General Medical Council to secure the maintenance of such a standard of proficiency as shall sufficiently guarantee the possession by candidates of the knowledge and skill requisite for the efficient practice of their profession. To this end the Council has formulated, for the guidance of the licensing bodies, a series of recommendations respecting such courses. These recommendations represent in general terms the minimum curriculum which, in the Council's opinion, should be required by the licensing bodies; and the Council notes with satisfaction that the regulations of the several bodies give effect to them. Cases may arise in which, during the present national emergency, the bodies deem it expedient to modify or suspend the application of the regulations to particular candidates; but the Council expects that all such cases shall be duly recorded and reported to the Council in the usual way. The Council feels sure that, in dealing with applications for modification or suspension of their regulations, the bodies concerned will recognise the importance, in the public interest, of maintaining unimpaired the present standard of knowledge and skill required of all who seek to be admitted to the status and privileges of registered practitioners; and will accordingly agree with the Council that it is desirable to secure, in every instance, that the requirements of the minimum curriculum are substantially fulfilled."

We have reason to believe that this statement has commended itself to the authorities concerned and to the profession at large. Multitudes of our medical brethren have nobly offered themselves for service with our troops at home and abroad. Many have already laid down their lives in the performance of that humane duty. The toll of war is not yet complete. We must face the certainty that ere long the ranks of our profession will be sadly depleted. Ample reserves are necessary to supply the places of those who fall on the field of honour. These reserves will be constituted by those whom we are now admitting to the status and privileges of registered practitioners. We shall best honour the memory of the fallen, and most surely safeguard the welfare of our forces and our people, if we do all in our power to secure that the men who enter the profession now are as fully and efficiently trained as their predecessors for the service they will soon be called to render. The need for efficient physicians and surgeons in the field and at home is not less urgent than the need for efficient soldiers and sailors. I have felt it my duty to press this consideration on senior students, who, though they have nearly completed their curriculum, are ready to forego the prospect of early qualification and to enrol themselves straightway in the combatant forces.

It is currently reported that, owing to the war, the number of students of all years enrolled for the present annus medicus is much below the average. If this be true, the risk of a serious shortage in the future supply of qualified practitioners would appear to be imminent. The data in the possession of the Council do not enable me to furnish an answer to the inquiries that have reached me from various public authorities interested in the subject. I have therefore thought it desirable to procure, so far as I could do so on my own responsibility, materials for a trustworthy estimate of the aggregate numbers likely to be ready for qualification in the next two or three years. The statistics, if I succeed in obtaining them, may prove of value from more than one point of view.

An inevitable dislocation of civil practice, both under the National Insurance Act and in general, arose in August and September from the mobilisation of practitioners, attached as surgeons to military hospitals and to Territorial and other service units. We have gratifying evidence that throughout the country the fraternal spirit shown by their colleagues did much to diminish the resulting difficulties experienced by such practitioners in providing for the care of their patients. In most localities a temporary working arrangement has been made by which the needs of the civil community will be met for the present. Plans have moreover been devised, in consultation with the National Insurance and the military authorities, which may, it is hoped, have the effect of removing certain defects in existing arrangements that actual experience has made manifest. The Executive Committee has had submitted to it various proposals bearing on these subjects, and so far as they lay within its province have offered advice upon them.

The magnificent rally of the Overseas Diminions to the defence of the empire has cheered but not surprised us at home. Their troops, fully equipped for service in Europe, are accompanied by a number of able and efficient surgeons. In virtue of the reciprocal relations which the Council has succeeded in establishing throughout the greater part of the empire, the majority of these surgeons are qualified for immediate registration at home, and are thus eligible for commissions in the Army Medical Service. Unfortunately some of the Provinces of Canada have so far omitted to entertain the overtures for reciprocity which this country has made to them. The result is that certain of the surgeons, fully qualified under the provincial law, find themselves debarred from acquiring what may be described as an Imperial status in the British Register. The remedy lies with the provincial authorities. I am not without hope that the representations which have been addressed to these authorities, in the interest of the Imperial services, will induce them to consider afresh the question of reciprocity. The war has made it clear that account must now be taken of its Imperial as well as its local aspects.

In India the legislation for the regulation of medical practice, of which I spoke last May, has now been extended to Madras. Communications from other parts of India bearing on the same subject have been under the consideration of the Executive Committee, and have been promptly dealt with. Negotiations with the India Office and the Government of India, which were entered into at the instance of the Examination Committee, in relation to Indian students of medicine and to members of the subordinate medical services, are still proceeding.

Sir Donald MacAlister then pointed out that the necessary preoccupation of Parliament with measures of emergency had prevented progress with the Midwives (Scotland) Bill and with the Privy Council measure for improving the procedure in the elections of the Direct Representatives. He said that the Highlands and Islands (Medical Service) Board had formed regulations for that service which contained no proposals to which the Council could object, and alluded also to the fact that certain unprofessional methods and laxities in the giving of certificates, which had been noted among practitioners in connexion with the carrying out of the National Insurance Act, had ceased to occur. He continued:—

On August 4th, when war was declared, the House of Commons ordered to be printed the report of the Select Committee on Patent Medicines.[1] The findings and recommendations of the committee deserve the Council's most careful attention. They testify in vigorous terms to the existence of a "grave and widespread public evil," and of an "intolerable state of things," for which new legislation, "rather than merely the amendment of existing laws, is urgently needed in the public interest." The Council, at the instance of its Unqualified Practice Committee, to which this report has been referred, has more than once expressed similar conclusions; but hitherto without practical result so far as the Legislature is concerned. It is earnestly to be desired that even in days like these, when the conservation of the public safety is the paramount objective of the Government, some earnest thought should also be given to the conservation of the public health, which is preyed upon by insidious and unscrupulous mercenaries.

The report of a Departmental Committee of the Board of Education, appointed to consider the "practice of the Board with regard to the acceptance of certificates from unregistered practitioners in dentistry," which was issued in July, may be taken as an indication that the State authorities recognise some at least of the dangers of *laissez faire* in the matter of unqualified practice. After stating that, "whatever may have been the intentions of Parliament in passing the Dentists Act of 1878, the position now is that no person may describe himself as a dentist or have his name inscribed in the Dentists' Register who has not obtained the qualifications required by the body entrusted by the State with the charge of the Register," the Departmental Committee adds: "It would very ill become the Board of Education to adopt a lower standard of general or special education than the minimum prescribed by the State." And the Committee's unanimous recommendation is to the effect that the Board should not agree to the request that the certificates of unregistered practitioners "should be accepted equally with those of registered dentists."

The recent changes in the regulations for death certification, issued by authority of the Registrar-General, mark a similar advance in the official position. We have reason to regret that progress is still so slow. But we have reason also to persevere in our efforts to accelerate it. *E pur se muove.*

Dr. LITTLE, in moving a vote of thanks to the President for his address, congratulated him on the fact that he had managed to leave Germany when the war broke out.

---

[1] THE LANCET, Sept. 5th (p. 653) and 12th (p. 702), 1914.

Penal Cases Committee.

Dr. Little was elected to the vacancy on the Penal Cases Committee occasioned by the death of Sir Christopher Nixon.

Degrees of Allahabad University.

The Executive Committee reported that it had considered an application from the University of Allahabad for the recognition of its degrees of M.B., B.S., for registration in the Colonial List of the Medical Register of the United Kingdom, and had adopted the following resolution :—

> That any person who holds the degrees of M.B., B.S., of the University of Allahabad shall be entitled to be registered in the Colonial List of the Medical Register, provided he satisfies the Registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886.

Restoration of Name to the Medical Register.

The PRESIDENT announced that the Acting Registrar had been directed to restore to the Medical Register the name of Mr. Walter Randall Knightley.

The Council adjourned.

WEDNESDAY, NOV. 25TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair. The whole of the sitting was occupied with the hearing of charges against practitioners.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregation held on Nov. 21st the following medical degrees were conferred :—

M.D.—L. M. Routh, Caius ; and C. Mackenzie, Emmanuel.
M.B.—J. Deighton, Trinity.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—W. Brown (Section II.), Oxford and King's College Hospital; C. H. Fischel (Section II.), Middlesex Hospital; G. F. Malden (Sections I. and II.), Royal Free Hospital ; H. R. Partridge (Sections I and II.), Leeds ; T. J. R. Scholtz (Sections I. and II.), Amsterdam ; and T. R. Scott. Edinburgh.

Medicine.—J. C. P. Bayley (Section II.), Manchester ; H. A. Cottin (Sections I. and II.), Caracas and Middlesex Hospital ; C. E. Clarke (Sections I. and II.), Bombay ; H. Morrison (Sections I. and II), St. Mary's Hospital ; H. R. Partridge (Sections I. and II.), Leeds ; C. H. Philips (Sections I. and II.), London Hospital; and F. Simpson (Section I.), Charing Cross Hospital.

Forensic Medicine.—R. H. Chadwick. Leeds ; H. A. Cottin, Caracas and Middlesex Hospital ; C. S. Dodson, Cambridge and University College Hospital ; C. J. G. Exley, University College Hospital and Leeds ; and J. D. Ferguson and H. R. Partridge, Leeds.

Midwifery.—C. E. Clarke, Bombay ; R. Curle, Guy's Hospital ; H. R. Partridge, Leeds ; and C. H. Philips, London Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery :—J. C. P. Bayley, W. Brown, C. H. Fischel, G. F. Malden, and H. R. Partridge.

UNIVERSITY OF LONDON.—At the Third (M.B., B.S) Examination for Medical Degrees for internal and external students held recently the following candidates were successful :—

Honours.—*Richard Alun Rowlands, London Hospital ; and †Douglas H. D. Wooderson, B.Sc., St. Bartholomew's Hospital.

* Distinguished in Medicine.
† Distinguished in Midwifery and Diseases of Women.

Pass.—Frederick Hubert Bray, London Hospital : Henrietta Frances Davies, London (Royal Free Hospital) School of Medicine for Women ; Arthur Rawdon Carrington Doorly, St. Thomas's Hospital ; John Beatson Dunning, Guy's Hospital ; Una Griffin, London (Royal Free Hospital) School of Medicine for Women ; Francis Joseph Hallinan. Charing Cross Hospital ; Mary Esther Harding, London (Royal Free Hospital) School of Medicine for Women ; Daniel Thomas Harris, Victoria University of Manchester ; Jessie Eva Hart, London (Royal Free Hospital) School of Medicine for Women ; Clement Hoyle Heppenstall, University of Leeds ; Rustam Merwan Kharegat, University College Hospital ; William Morris Lansdale, Guy's Hospital ; Leon Levene, University College Hospital ; Andrew Carey McAllister, King's College Hospital ; Helen Marion Macpherson Mackay and Ethel May Magill, London (Royal Free Hospital) School of Medicine for Women ; William John Morris University College Hospital ; Margaret Russell Paterson and Edna Mary Powell, London (Royal Free Hospital) School of Medicine for Women ; John Bromley Rawlins, St. Mary's Hospital ; Reginald Hugh Simpson, St. Bartholomew's Hospital ; Grace Stapleton, London (Royal Free Hospital) School of Medicine for Women ; Ernest Haines Walker. St. Thomas's Hospital ; and Thomas Burges Welch, St. Bartholomew's Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Army Medical Officers and Income Tax.

SOME concession in the matter of income tax is to be made by the Government in the Finance Act to medical officers who have joined the armed forces of the Crown in consequence of the war. Professional men are assessed on an average of three years' earnings, but it was pointed out during the debate in committee on the Finance Bill on Tuesday evening that it would be most unfair to apply this method of assessment to men who for a large part of the current year have sacrificed a big share of their professional income in order to serve in the field.—Sir JOHN SIMON, the Attorney-General, admitted the force of this contention. The amendment made in the Bill at his instance laid down that officers and men who had served or were serving at home or abroad in the military or naval forces of the Crown in connexion with the present war would not be taxed either for income tax or super tax on the three years' average, but only upon the income actually earned in the present financial year (1914–15). The same concession was made to those who had been engaged in connexion with the war in any work abroad of the British Red Cross Society, the St. John Ambulance Brigade, or kindred organisations. The Attorney-General was asked how this concession would affect medical men serving with the forces. He replied that all such officers serving under military law would receive the concession whether serving at home or abroad.

HOUSE OF COMMONS.

THURSDAY, NOV. 19TH.

Army Medical Officers.

Sir H. RAPHAEL asked the Under Secretary of State for War whether retired army medical officers holding retired pay appointments of medical officer in charge of troops and military hospitals at depôts necessitating in peace time an inconsiderable amount of work, and now, since the commencement of the war, requiring all-day service and constant orderly duty day and night owing to the increase of work and expansion of hospital duty, had been refused kit allowance and the same rate of pay granted to retired medical officers who had been recalled to duty ; and, if so, whether he would consider the justice and advisability of equalising the financial position of these two classes of officers.—Mr. H. BAKER (on behalf of Mr. TENNANT) replied : These officers, in common with other retired officers who were in the employment of the War Department in peace, are being treated in accordance with the regulations under which they accepted their appointments. If there are any grounds for varying the regulations they shall be considered.

Sir H. RAPHAEL : Can the honourable gentleman say why, if this matter has engaged the attention of the War Office, have they failed to acknowledge my letters giving full reasons for the proposed equalisation of scales of payment ?—Mr. BAKER : Those are the regulations under which they were employed.

Sir H. CRAIK : Is it not the case that these men, who have had long experience, are at a salary of £150 working 12, 13, and 14 hours per day ?—Mr. BAKER : I do not know whether it is so. It may be that they are working long hours, but many people are. The regulations under which they are serving are regulations which they have accepted. If there is a good case for altering them it will be considered.

Sir H. CRAIK : Is it not the case that temporary doctors who are acting in their places are receiving as much as £1 4*s*. per day whilst these men are only receiving a salary of £150 ?—Mr. BAKER : If the honourable gentleman would submit grounds on which he thinks the regulations should be altered I promise him they will be considered.

The Health of the New Army.

Mr. MORRELL asked the Under Secretary of State for War whether his attention had been called to the number of cases of pneumonia that had recently occurred in some of the camps in which the new army was being trained ; and whether he would grant a return showing the health of the troops in the various camps.—Mr. TENNANT answered : The returns of admissions to hospitals regularly come before us. My honourable friend is not correct in thinking that the number of cases of pneumonia is abnormal. There has been no rise in the admission ratio in spite of the fact that a large proportion of troops are under conditions of camp life. There is no undue prevalence of infectious disease anywhere, and my noble friend being able to give this assurance, does not think that the suggested return would be in the general interest.

Monday, Nov. 23rd.

Medical Arrangements of the New Army.

Mr. Hinds asked the Under Secretary of State for War what arrangements were being made for providing a medical service for the new armies; and, pending the organisation of such a service, what provision was made for the treatment of troops in the new battalions or brigades.—Mr. Tennant answered: The new army will be provided with medical arrangements on the same basis as the Expeditionary Force. Large training establishments have been formed at which the subordinate personnel is being instructed in their active service duties. Pending the completion of these arrangements the new army is receiving medical attendance on exactly the same lines as the regular army in times of peace. Temporarily commissioned officers in the Royal Army Medical Corps and locally employed civil practitioners have been engaged in sufficient numbers to meet all requirements, and nearly 100 of the Royal Army Medical Corps Reserve of Officers have been recalled to duty. So far there has been no difficulty in securing the services of a sufficient number of fully qualified medical men, and it is not anticipated that there will be any shortage in the immediate future. All the military hospitals in the country have been very greatly expanded, and several large civil and private hospitals are working in conjunction with them. Up to the present there has been no lack of hospital accommodation.

Tuesday, Nov. 24th.

Medical Attendance for Soldiers' Dependents.

Sir H. Craik asked the Secretary to the Board of Education, as Vice-Chairman of the Committee with regard to the provision of free medical attendance and drugs when necessary to the dependents of men serving with the army, whether any arrangements had been arrived at as to the offer of the British Medical Association to provide free medical attendance to such dependents, and what arrangements had been made for the supply of the necessary medicines.—Dr. Addison replied: The Special Committee set up for the purpose have prepared a scheme for utilising the generous offer of the British Medical Association, and have issued instructions to Local Representative Committees in England and Wales, together with a supply of special medical books for issue to suitable dependents of men serving with the army or the navy. The scheme is now in operation throughout England and Wales, except in a few areas where a local scheme had been adopted. The local arrangements vary, but as a rule the books, which are accepted as evidence of *bona fides* by doctors and chemists working under the scheme, are issued by the Local Representative Committee, assisted by the Soldiers' and Sailors' Families Association. The scheme has also been brought into operation in Scotland, where it is being worked by the Soldiers' and Sailors' Families Association, The Pharmaceutical Society of Great Britain generously offered on behalf of their members to supply the necessary medicines and appliances at cost price. The cost price of medicines and appliances supplied under the scheme is being defrayed from a grant made out of the Prince of Wales's Fund. The work of checking and pricing prescriptions is being undertaken at considerable expense by the Pharmaceutical Society under a system approved and inspected by the Committee.

BOOKS, ETC., RECEIVED.

Arnold, Edward, London.
A System of Clinical Medicine dealing with the Diagnosis, Prognosis, and Treatment of Disease, for Students and Practitioners. By Thomas Dixon Savill, M.D. Lond. Fourth edition, thoroughly revised. Price 25*s.* net.

Baillière, Tindall, and Cox, London.

STOCKWELL.—On Nov. 20th, at Bruton, Somerset, Frederick Stockwell, M.D. Lond., aged 76 years.

YEO.—On Nov. 20th, suddenly, .I Burney Yeo, M.D., F.R.C.P. Lond.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

THE ATTRACTIONS OF DAVOS.

IN his annual report, just received at the Foreign Office, Dr. Bernard Hudson, the British Consul at Davos, writes that in the year 1913 there were 10,936 invalids resident, besides 12,595 tourists and 8101 long-stay visitors—total 31,632, as compared with 31,055 in 1912. Of these, in 1912 2099 were British, while in 1913 the number of British was 2236, thus showing an increase of 137. This (observes Dr. Hudson) is eminently satisfactory, and all the more so in view of the fact that for some years past the numbers of British visitors have been steadily declining; in 1910 they numbered 2513, in 1911 2267, and in 1912 only 2099, this latter being the smallest British total since records have been officially kept. This decrease in the number of British visitors may be put down partly to the desire to favour home resorts, of which many have sprung up of late years, and also partly, no doubt, to the erroneous impression prevailing at home that owing to the number of invalids Davos is not a safe place to go to. It only requires a visit to dispel these ideas. However, the fact that the numbers of British have increased in 1913, and also again this year up to March 31st, serves to show that the merits of the dry, sunny, windless Alpine climate are once again beginning to make their claim felt, especially as regards the treatment of pulmonary tuberculosis.

Davos has developed to an extraordinary degree as a ski-ing centre of late years, and now an increasing number of British people go for this particular sport. There are large numbers of both long and short tours to choose from. Davos may be called the home of British skating, and it is here that this particular branch of the art is seen to the best advantage. The club is in a very flourishing condition. Bobbing and tobogganing always form a prominent part of the winter sports, and the two excellent runs—i.e., Klosters and the Schatzalp—are always much in demand. There is also a good rink for curling, capable of accommodating four games simultaneously.

The Queen Alexandra Sanatorium has had a highly successful year, and many invalids, who otherwise would not have been able to go to Davos, have felt the benefit of this excellent institution. The new wing of 18 beds was opened last year, while this year a fine suite of up-to-date medical rooms has been added, and also a new X ray room. The project for making a kur-park for the use of summer visitors has been passed and the work begun. This will be a great boon to the place and will, it is hoped, attract visitors during the summer.

A SOLDIER'S FRENCH BOOK.

THE *Soldiers' English and French Conversation Book*, compiled by Walter M. Gallichan (London: T. Werner Laurie. Pp. 142. Price 7*d.* net), should prove of considerable service to those for whom it is intended. It differs from all other conversation books in the important particular that all its vocabulary and all its phrases deal with only military subjects or with a selection of everyday subjects concerning which Tommy Atkins is particularly likely to wish to communicate his ideas to French people, military or otherwise. The little book deals with landing, marching, train, camping, transport, action, convoy, aviation, trenches, wounds, &c., and includes ordinary conversation dealing with food, smoking, money, weights and measures, &c. There are also considerable vocabularies of strictly military terms and of everyday words. A phonetic pronunciation is given which, on the whole, is fairly good. The correspondence between symbols and pronunciation is, however, so arbitrary that without a distinct prior agreement, acquired by ear and eye together, as to what symbols shall stand for in the way of sound, there is little reasonable ground to hope that two people would interpret the transliteration alike. On the whole, however, a Frenchman would be able to recognise what was meant in French by an English person making the effort to pronounce the phonetic forms as though they were English words.

TO CYCLIST MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—Would one of your readers tell me what are the duties of the medical officer to a cyclist battalion, who is not a member of the Royal Army Medical Corps?

I am, Sir, yours faithfully,
SEPTOCYCLE.
Nov. 24th, 1914.

A MISSING OFFICER.

WE are asked to state that if any member of the Royal Army Medical Corps has heard or knows anything of the whereabouts of Second Lieutenant Mark R. Pease, 1st Battalion East Yorkshire Regiment, who has been missing since Oct. 20th, it would be a great kindness if he would communicate with his father, Colonel Pease, Beverley, East Yorks. Mr. Pease, at the time he was reported missing, was engaged in hand-to-hand fighting near Prémesques, half way between Lille and Armentières.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In a notice sent you recently of the Alvarenga prize of the College of Physicians of Philadelphia there was an error in the title of Dr. Sheffield's paper; it should read as follows: "Idiocy and Allied Mental Deficiencies in Infancy and Early Childhood." I shall be greatly obliged if you will make this correction.—I am, Sir, yours faithfully,

FRANCIS R. PACKARD, M.D.,
Secretary, College of Physicians of Philadelphia.
Philadelphia, Nov. 7th, 1914.

AMBIGUITY.

WE observed the following paragraph in an evening newspaper this week:—

> "The intolerable nuisance of mud-splashing by motor-cars" is to be discussed by the Westminster City Council with a view to the use of a contrivance to prevent it being made compulsory.

It must be a curious contrivance.

A GOLD medal is to be presented by Mr. Henry S. Wellcome to Dr. Frederick B. Power to commemorate his directorship of the Wellcome Chemical Research Laboratories for 18½ years. In addition Mr. Wellcome is causing a life-size portrait of Dr. Power to be painted.

R. L. G.—The official "Manual of Elementary Military Hygiene," price 6*d.*, can be obtained in London from Wyman and Sons, or abroad through agencies of T. Fisher Unwin.

Diwan Chand.—The publisher is Mr. William Heinemann, Bedford-street, London, W.C. The book could probably be obtained through Messrs. Butterworth and Co., of Calcutta.

K.—We know of no suitable work.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—M. de Lange: On the Thermophone—a New Form of Telephone.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. R. J. Albery, Lond.; Dr. David Anderson-Berry, Lond.; Mrs. Alec-Tweedie, Lond.; Admiralty, Medical Department, Lond., Director-General of; Dr. Edwin Ash, Lond.

B.—Messrs. Burroughs Wellcome and Co., Lond.; Beckett Hospital, Barnsley, Hon. Secretary of; Messrs. W. H. Bailey and Son, Lond.; Major R. J. Blackham, R.A.M.C., Simla; Mrs. Behnke, Lond.; Messrs. T. B. Browne, Lond.; Messrs. Butterworth and Co., Lond.; Mr. P. Bouchard, Casablanca; Mr. J. Philip Buckley, Manchester; Mr. H. Haward Bywater, Liverpool; Dr. H. N. Burroughs, Lond.; Mr. C. Birchall, Liverpool; Dr. H. E. Biggs, Cardiff; British Fire Prevention Committee, Lond., Registrar of; Beckenham Urban District Council, Clerk to the; Blackburn Guardians, Clerk to the; Bristol General Hospital, Secretary of; Birkenhead and Wirral Children's Hospital, Hon. Secretary of; British Red Cross Society, Lond., Secretary of; Dr. G. S. Buchanan, Lond.; Dr. F. Milnes Blumer, Stafford; Mr. H. G. Bonett, Watford.

C.—Messrs. E. Cook and Co., Lond.; County Asylum, Prestwich, Clerk to the; Mr. C. Clarke, Lond.; College of Physicians of Philadelphia, Secretary of; Messrs. Carnrick and Co., Lond.; Mrs. E Chew, Belfast; Mr. G. Matheson Cullen, Edinburgh; Chelsea Hospital for Women, Secretary of; Calcutta, Health Officer of; Mr. Diwan Chand, Lahore; Messrs. P. and D. Colnaghi and Obach's Galleries, Lond.; The Church Army, Lond., Literary Secretary of; Dr. C. Willett Cunnington, Lond.

D.—Dr. Arthur T. Davies, Lond.; Messrs. Dawson and Sons, Lond.; Messrs. A. De St. Dalmas and Co., Leicester; Messrs. Dennis and Holloway, Scarborough; Lieutenant M. Donaldson, R.A.M.C., Havre; Mr. H. Dickinson, Lond.; Sir H. Bryan Donkin, Lond.; Derby Mental Hospital, Clerk to the; Captain A. H. T. Davis, R.A.M.C., France.

E.—Mr. A. R. Elliott, New York; East Suffolk and Ipswich Hospital, Ipswich, Secretary of.

F.—Dr. Y. Farag, Cairo; Fife District Asylum, Cupar, Clerk to the; Messrs. Fannin and Co., Dublin; The Future Career Association, Lond., Director of; Captain C. M. Fegen, R.A.M.C.(T.), Lond.

G.—Messrs. Gale and Co., Lond.; Government Committee on the Prevention and Relief of Distress, Lond.; Dr. M. H. Gordon, Lond.; Dr. Arthur Greene, Norwich; Dr. Simonds Gooding, Lond.; Dr. T. Wardrop Griffith, Leeds; Sir Rickman Godlee, Bart., Lond.; Dr. W. Herbert Gregory, Beverley; Captain H. Gall, R.A.M.C., Sialkot, India; Gloucestershire Royal Infirmary, Gloucester, Secretary of; Govan District Asylum, Hawkhead, Medical Superintendent of; Mr. H. Ginn, Worcester.

H.—Mr. C. A. Hoefftcke, Lond.; Mr. Frank Hastings, Lond.; Dr. W. Harmens, Addlestone; Dr. C. F. Harford, Lond.; Mr. H. W. Hull, Lond.; Hertford Street Motor Co., Lond., Secretary of; Lieutenant-Colonel A. G. Hamilton, R.A.M.C.(T.F.), Bungay; Lieutenant-Colonel F. W. Davie Harris, Lond.; Messrs. Harker, Stagg, and Morgan, Lond.; Halifax Guardians, Clerk to the.

I.—Dr. C. E. Iredell, Lond.; Insurance Committee for the County of London, Clerk of; Incorporated Liverpool School of Tropical Medicine, Secretary of.

J.—*Journal of the American Medical Association*, Chicago; Professor Jacobs, Lond.; J. F. N.; Dr. F. Wood Jones, Lond.; Jenner Institute for Calf Lymph, Lond.

K.—Messrs. H. S. King and Co., Lond.; King Edward VII. Welsh National Memorial Association, Cardiff, Secretary of; Mr. Grenville Kleiser, New York City; Mr. W. Kingham, Eastbourne; Mr. W. Ker, Lond.

L.—Major J. C. H. Leicester, I.M.S., Southampton; London Press Exchange, Manager of; Leicester Royal Infirmary, Secretary of; Lieutenant B. T. Lang, R.A.M.C., France; Mr. P. Lockhart Mummery, Lond.; Leeds General Infirmary, General Secretary of; Dr. C. E. Lea, Manchester; Leeds Education Committee, Secretary of.

M.—Sir J. McFadyean, Lond.; Mr. M. G. McElligott, Wigan; Dr. T. McCririck, Whitehaven; Dr. Henry MacCormac, Lond.; Sir Philip Magnus, M.P., Lond.; Maruyen Co., Tokyo; Dr. A. Mertens, Brighton; Lieutenant-Colonel Charles Monk, Lond.; Dr. C. A. Mercier, Parkstone; Dr. Moraes Manchego, Lisbon; Dr. F. Masschelein, Cardiff; Mr. John J. McNaboe, Lond.; Dr. H. Crichton Miller, Lond.; Dr. G. Michael, Beni-Souef; *Midland Counties Herald*, Birmingham; Messrs. Thomas Murby and Co., Lond.; Manchester Guardians, Clerk to the.

N.—Newsagents' Booksellers,' and Stationers' National Union, Lond., Secretary of; *The Nursing Times*, Lond., Secretary of; North Ormesby Hospital, Middlesbrough, Secretary of; Dr. W. Niccol, Gloucester; National Health Insurance Commission (Scotland), Edinburgh, Secretary of.

O.—Dr. J. O'Conor, Buenos Aires; Oxford University Press, Lond.

P.—Mr. J. Pitcairn, Lond.; The Parkinson Stone Co., Lond.; Sir R. Douglas Powell, Bart., Lond.; Professional Classes War Relief Council, Lond., Hon. Secretaries of; Panama-Pacific International Exposition, San Francisco, Commissioner of; Mr. J. Herbert Parsons, Lond.

R.—Mr. M. A. Rubin, Brooklyn; Royal National Hospital for Consumption for Ireland, Dublin, Secretary of; Royal Mail Steam Packet Co., Lond.; Messrs. Robertson and Scott, Edinburgh; Mr. L. B. Rawling, Lond.; Messrs. Richardson and Co., Lond.; Royal Society of Arts, Lond.; Dr. Henry Rundle, Southsea; Mr. Noel R. Rawson, Pentre Broughton; Messrs. Reynolds and Branson, Leeds.; Royal Sanitary Institute, Lond.

S.—Mr. J. Ledger Smith, Cardiff; Mr. F. L. Simons, Edinburgh; Mrs. Simpson, Nottingham; Captain J. L. Sen, I.M.S., Brockenhurst; Smith's Advertising Agency, Lond.; Sunderland Post Co., Manager of; Mr. C. Sargeant, Lond.; Captain A D. Stirling, R.A.M.C., France; Dr. F.J. Scrimgeour, Alexandria; Surrey County Council, Kingston-upon Thames, Clerk to the; Mr. Walter G. Spencer, Lond.; Dr. E. H. Snell, Coventry; County of Stafford, Clerk of the Peace and Clerk of the County Council of, Stafford; Society of Apothecaries of London, Secretary of; St. John's Hospital, Lond., Secretary of; Salford Royal Hospital, Secretary of; Sheffield Children's Hospital, Secretary of; South Yorkshire Asylum, Wadsley, Clerk to the; Salford Guardians, Clerk to the; Dr. Francis E. Shipway, Lond.; Dr. G. F. Darwall Smith, Lond.

T.—Messrs. Tindall and Jarrold, Chelmsford; Taunton and Somerset Hospital, Secretary of; Dr. P. C. E. Tribe, Lond.; Mr. C. Townshend, Lond.; Major Hugh N. Taylor, R.A.M.C., Ebbw Vale; Messrs. Raphael Tuck and Sons, Lond., Managing Director of; Dr. N. Tirard, Lond.; Mr. Herbert Tilley, Lond.; Staff-Surgeon Turner, R.N., Lond.; Tunbridge Wells General Hospital, Secretary of.

U.—University of London, Principal of.

W.—Worcester County and City Asylum, Powick, Clerk to the; Wolverhampton General Hospital, Secretary of; Messrs. Wilding, Bishop, and Co., Lond.; Dr. M. Wiener, St. Louis; Messrs. J. Woodhead and Sons, Huddersfield; Wills, Ltd., Lond.; Mr. J. W. Woodruff, Ryde; Monsieur A. Willis, Cardiff; War Office, Lond., Secretary of; Dr. E. M. Wyche, Nottingham; Walter Scott Publishing Co., Lond.; Dr. M. Van den Wouwer, Birmingham; Wellcome Chemical Research Laboratories, Lond., Secretary of; Dr. Albert Wilson, Lond.; The Wellcome Bureau of Scientific Research, Lond., Director-in-Chief of; W. A. M.; Messrs. J. Williams and Son, Bradford; West Ham and Eastern General Hospital, Secretary of; Mr. C. G. A. Wyatt, Lond.

Y.—York County Hospital, Secretary of; Dr. Augustine M. Fernandez de Ybarro, Havanna.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. T. L. Ashforth, Doncaster; Dr. G. N. Adams, Porthcawl; Ashwood House, Kingswinford, Medical Superintendent of; Mr. E. Arnold, Lond.

B.—Dr. W. H. Bourke, Lond.; Booth Steamship Co., Liverpool; Berrow's Worcester Journal Co., Worcester, Manager of; Messrs. Blades, East, and Blades, Lond.; Mr. J. D. Bickett, Strathblane.

C.—Cumberland, &c., Lunatic Asylum, Carlisle, Clerk to the; Carnarvonshire Education Committee, Carnarvon, Secretary of; Messrs. Callard, Stewart, and Watt, Lond.

D.—Messrs. J. L. Denman and Co., Lond.; Dr. G. Dickson, Lond.; Davis Gas Stove Co., Lond.; Dundee Royal Infirmary, Secretary of; Duff House, Banff, Secretary of; Rev. W. Dale, Lond.; Devonshire Hospital, Buxton, Secretary of; Mr. W. O. Dixon, Lowca.

E.—Dr. G. N. Edmondson, Newcastle, Staffordshire.

G.—Mr. J F. Gelt, Nottingham; Gateshead Corporation, Clerk to the; Captain R. L. Gamlen, I.M.S., Grouville; Great Yarmouth Hospital, Secretary of.

H.—Messrs. Harris and Gillow, Lond.; H. G. M.; Hartlepools Hospital, Secretary of.

I.—Ilford, Ltd., Lond., Secretary of; Invernith Sanatorium, Colinsburgh, Secretary of.

J.—Messrs. Jacob and Johnson, Winchester; J. A. B.; Dr. I. W. Joynt, Lond.; J. W.

K.—Kilmarnock Infirmary, Secretary of; Mr. F. Keppel, Rothsay.

L.—Mr. T. S. Logan, Stone; Mr. H. K. Lewis, Lond.; Leeds Public Dispensary, Secretary of; Dr. J. Lambert, Shotley; Mr. A. Lupton, Gosport; Liverpool Stanley Hospital, Secretary of; Liverpool Guardians, Clerk to the; London Temperance Male and Female Nurses' Co-operation, Secretary of; Mr. H. A. Lindsey-Birchall, St. Day.

M.—Manchester Corporation, Treasurer to the; Mansfield, &c., District Hospital, Secretary of; Messrs. J. Menzies and Co., Glasgow; Colonel Magill, Lond.; Dr. C. N. Millar, Netley; Messrs. J. Menzies and Co., Edinburgh; Manchester Hospital for Consumption, Secretary of,

N.—Nurses' Co-operation, Lond., Secretary of; Newcastle-on-Tyne Corporation, Clerk to the; New Mental Nurses' Co-operation, Lond., Secretary of; Nottingham General Hospital, Secretary of.

O.—Mr. J. O'Shea, Birmingham; O. H. H.

P.—Planet Foundry, Manchester; Dr. J. R. Perdran, Dorchester; Mr. Walter Pratt, Lond.; Dr. T. W. Parry, Lond.

Q.—Queen's University, Belfast, Registrar of.

R.—Dr. A. K. T. Raw, Hyderabad; Dr. E. B. Reckitt, Little Hadham; Royal Portsmouth, &c., Hospital Secretary of; Richmond Royal Hospital, Secretary of; Mr. G. A. Russell, Oldbury; Royal Devon and Exeter Hospital, Secretary of; The Retreat, York, Secretary of.

S.—Messrs. Shaw and Sons, Lond.; Swansea Guardians, Clerk to the; Mr. A. J. L. Speechly, Hutti; Dr. J. Sutherland, Leeds; Staffordshire County Council, Cheddleton, Clerk to the; St. Mary's Hospital for Women, &c., Lond., Secretary of.

V.—Victoria Hospital, Blackpool, Secretary of.

W.—West Bromwich District Hospital, Secretary of; W. C. H.; West Riding County Council, Wakefield, Treasurer to the.

The Croonian Lectures

ON

MODERN ASPECTS OF CERTAIN PROBLEMS IN THE PATHOLOGY OF MENTAL DISORDERS.

Delivered before the Royal College of Physicians of London,

BY EDWIN GOODALL, M.D. LOND., B.S., F.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, CITY OF CARDIFF MENTAL HOSPITAL.

LECTURE I.

SIR THOMAS BARLOW AND GENTLEMEN,—When I was honoured with an invitation to deliver these lectures before the College I deemed it a duty to make it clear that it would not, in my judgment, be possible for any one whose work lay in the domain of psychiatry to bring before you at the present time an array of substantial results, based upon scientific research, such as would for a moment compare with the results available for a general pathologist, a bacteriologist, or a worker in the general domain of pathological chemistry. This disability is doubtless recognised by those whom I have the honour to address; briefly, it depends, firstly, upon the inherent difficulties of the problems of the pathology of mental disorders, and, secondly, upon the deplorable separation of psychiatry from the other branches of medicine, in this country more especially—a separation which I am glad to believe is nearing its termination. In view of the comparative paucity of facts available for the purposes of my theme it is necessary in these lectures that my range should be somewhat wide, and I shall have, broadly speaking, to deal with the results of pathological and bacteriological research, with problems of metabolism, with chemical and serological observations, and with certain therapeutic measures based upon observations in clinical pathology.

MORBID HISTOLOGY IN MENTAL DISEASE.

My impression from a survey of my experience of 24 years is that the attention of workers in the field of the pathology of insanity was in the main devoted to the morbid anatomy and histology of the brain until about 15 years ago, when the output of work in this domain showed signs of diminishing, and attention was diverted to the problem of pathological causation. Already 20 years ago dissatisfaction with the results of histological research was expressed, and the advent of the worker in the field of biochemistry was desired. The histological work of those who had gone before was recognised, it need not be said, as indispensable; whilst we were not so foolish as to believe that it was complete, it was nevertheless felt that, even in comparison with other diseases, the knowledge we possessed of the morbid histology of the brain in mental disease was not mean, and that the time had arrived when following the rational course, we should search for the pathological factors which had expressed themselves in the modes with which we were familiar. There remained, and there still remains, the problem as to the degree of responsibility of the histological lesions for some of the symptoms, perhaps characteristic symptoms, of this or that kind of insanity, by virtue of specific localisation of lesions in specific kinds of insanity.

At the present time we have to record that there are in most cases of mental disease uncharacteristic brain changes, but, largely owing to the powerful impetus given to histological research by the work of Alzheimer and Nissl and their pupils, characteristic brain changes have been shown in mental disease associated with syphilis, in the progressive dementia which accompanies some cases of arteriosclerosis and in senile dementia. On the other hand, the histological lesions found in the following clinical kinds of insanity are not characteristic: the kinds grouped under the term "dementia præcox," the alcoholic insanities, so-called manic-depressive insanity, acute delirious mania, insanity with epilepsy, though it be granted that in the last-mentioned instance a diffuse cerebral gliosis is found in cases dying from intercurrent disease after years of the malady. There is no evidence of characteristic localisation of the lesions found in the brain in the psychoses, either as regards the brain as a whole or as regards layers of the cortex cerebri, or constituents of the cortex, unless the involvement of the mesodermal elements in the psychoses primarily due to syphilis or associated with trypanosomiasis are so considered.

THE DEMENTIA PRÆCOX GROUP OF CASES.

I am not, I think, justified in detaining you with observations upon morbid histology in mental diseases further than is necessitated by a reference to the particular cases of, respectively, the dementia-præcox group and dementia paralytica. In studying the pathological anatomy of the cases nowadays grouped under the name "dementia præcox" we are faced with the difficulty that death seldom occurs in an early stage of the disease, and when it does it is due to intercurrent maladies, especially tuberculosis, which may themselves be partially responsible for the morbid appearances. The disease is not due to lethal causes; incidentally, the same is true of other psychoses, such as the systematised delusional disorders, and even manic-depressive insanity, as a rule. Zingerle[1] rightly points out that one must further discount appearances which may well be referable to mere congenital defect of development. There being no characteristic anatomical picture for the disorder as a whole, its subdivision, clinically, into three groups obtains of course no support from the standpoint of pathological anatomy. Some of the best descriptions of individual cases (Zingerle, Klippel and Lhermitte,[2] Goldstein,[3] Fioli[4]) are concerned with the katatonic variety of the disease. The points to be noted for verification from the observations made up to the present are: that, at any rate for the variety mentioned the lesions—of the individual elements—which are in no way peculiar, but are those found in many acute and recent mental disorders (degenerative conditions, as shown by modern methods in nerve- and glia- cells), are found throughout the brain, the cerebellum, and the basal ganglia; that they are especially pronounced in the deeper layers of the cortex cerebri; that they concern the ectodermal elements (degeneration) especially and the mesodermal to a much less extent (absence of inflammation). Should these observations be confirmed they would afford a means of distinguishing anatomically between this clinical variety of dementia præcox and such diseases as dementia paralytica, insanity due to lues cerebri, to arterio-sclerosis, and to chronic alcoholism, in which vascular and perivascular changes are marked. If confirmed, they would point to the conclusion that maladies which are associated with lesions so diverse must be unlike in pathogenesis.

DEMENTIA PARALYTICA.

In regard to the morbid anatomy of dementia paralytica, it is admitted that whilst none of the macroscopic or microscopic lesions is pathognomonic, these together form a whole which is characteristic. To the naked eye, the combination of the indications of long-standing lepto-meningitis, especially pronounced over the fronto-parietal area, of cortical erosions, of wasting of the prefrontal gyri and granularity of the ependyma of the ventricles, is characteristic. Histologically the diffuse nature of the infiltration, by products of inflammation, of the vessel-walls, traceable throughout the vessels, including the finest, the tendency of the infiltration to keep to the vessel-walls and perivascular area, the superabundance of plasma cells: these are characteristic. Some might further claim that the multiplicity, the gravity, and the widespread distribution of all the lesions throughout the nervous system are characteristic. As to the controversy formerly waged, and as late as ten years ago, as to whether the primary lesion in dementia paralytica were vascular or parenchymatous, meaning by the latter a primary degeneration of the neurones, one hears nothing now. The dogma respecting primary degeneration was harmful, like other dogmata; in this instance it diverted attention from inquiry into a toxi-infective causation. Spielmeyer,[5] in 1910, described the histological changes in an early case of the disease, dead of an intercurrent malady, in which there were inflammatory changes in some parts of the cortex and degeneration of the nerve tissue in other parts. He further refers to a case reported by Alzheimer, one of long standing, in which extensive nerve tissue degeneration existed with very little vascular change. Vascular changes and parenchymatous degeneration are independent of each other to some extent. The question of their relationship appears insignificant, overshadowed by the problem of their common pathogenesis. The proclivity of the frontal lobes to the disease remains unexplained, except on the views of Dr. Ford Robertson, according to which they are exposed to early infection by the diphtheroid organisms described by him, since these are traceable to the brain *viâ* the nasal mucosa, and the frontal lobes are in contiguity with the cribriform plate of the ethmoid.

Lesions in Dementia Paralytica and Cerebral Lues.

One has selected the frontal gyri almost as matter of course as the most likely ones in which to find the spirochæta pallida, and recent writers appear to find the organism with less difficulty in them than elsewhere. Having regard to the fact that the morbid histology of the brain in dementia paralytica, and in diffuse cerebral lues, I think I may also say, was—if we except plasma cells and rod cells—well known to pathologists in 1892 (I select that date with confidence in respect to dementia paralytica, at any rate, as at that time those of us who were taught by Bevan Lewis at the West Riding Asylum knew almost as much concerning the morbid histology as we do now), it is somewhat surprising to me that I cannot remember that anyone then pointed out the difficulty of differentiating between these two conditions by histological examination. The failure to recognise, or at any rate to lay stress upon, the resemblance between these two histological pictures I ascribe to the absence of coördination between workers in psychiatry and neurology, and to the fact that the importance of syphilis in the pathogenesis of dementia paralytica was not then recognised. It was not, I think, until by patient clinical observation, and inquiry into the histories of cases, evidence of syphilis was found in a large proportion that such evidence was sought for by the methods of morbid histology; and no doubt interest in this inquiry was further promoted by the results obtained by the application of the method of complement-deviation to the serum and cerebro-spinal fluid of general paralytics.

Giljarowsky,[6] in 1911, thought the conclusion justified that diffuse syphilitic changes in the brain and meninges are difficult or impossible to distinguish from the changes commonly associated with dementia paralytica; only local conditions, such as gummata in different stages, can with certainty be distinguished. He describes an interesting case in which clinically there were first symptoms of cerebral syphilis and later of dementia paralytica; at the necropsy were found histological changes ascribable to syphilis and others usually regarded as characteristic of dementia paralytica; the former, however, appeared to be of longer duration. The author considers this to be a case of combined syphilis and general paralysis. At the present day some would no doubt be disposed to regard the morbid condition as due in its entirety to syphilis. Cerletti[7] (1913) describes infiltration of the adventitia of the cerebral vessels, and of the pial vessels, by lymphocytes and plasma cells, and proliferation of the glial elements, in meningo-encephalitis of syphilitic origin, indistinguishable from the lesions found in dementia paralytica. He observes that the treponema pallidum is very rare in cerebral syphilis in the adult; some of us know the difficulty of finding it in the other condition. Landsbergen[8] (1912) maintains that there occur often in one microscopic field the characteristic changes of tertiary lues and those of so-called metasyphilis. Sträussler[9] (1911 and 1912) described six cases in which syphilitic lesions—such as meningitis and miliary gummata—coexisted with changes typical of dementia paralytica. Marinesco and Minea[10] (1913) also point out the resemblance between the histological pictures in the cases in question. I cite the above work as indicating how, in recent times, and in the light of better knowledge of the pathology of dementia paralytica, a close relationship has been found between the lesions of diffuse cerebral lues and of so-called metasyphilitic disease of the brain. The importance of the plasma cells in the latter has been exaggerated. I have already alluded to the extraordinary abundance of these elements in the brain of the general paralytic, and this appears to be a characteristic of dementia paralytica; I believe also of sleeping sickness. But they are not peculiar to any special disease; they have been described in cerebral lues, in non-specific encephalitis, and in non-specific foci of inflammation in the central nervous system.[11 12] They appear to constitute a mode of reaction to different toxic agents.

Relations of Dementia Paralytica and Cerebral Syphilis.

The demonstration of the existence in certain cases of diffuse cerebral lues and dementia paralytica of the same cerebral lesions, and the demonstration of mixed histological lesions, illustrating both conditions, in the same brain, leads to the suggestion that dementia paralytica is merely an unusually late manifestation of syphilis of the brain. The number of syphilitics who develop tertiary lesions in the brain is rare; according to Henschen,[13] of 754 only 17·85 per cent. do so. The number developing dementia paralytica is still rarer; statistics, to which I presently refer, place the incidence at 4–5 per cent. As to development of dementia paralytica in cases of cerebro-spinal lues, Mattauschek and Pilcz[14] found that of 116 cases of the latter condition only 2 got the former. This observation is particularly interesting. It is in keeping with the clinical, anatomical, and histological evidence furnished by typical cases of dementia paralytica, which demarcates the condition from cerebral lues. To this has to be added the evidence furnished by the studies in the metabolism of nervous and mental disorders which have been made in quite recent times, which, although doubtless in need of confirmation and amplification, go to show that in dementia paralytica there are well-marked disturbances which are not found in lues cerebri, so that some additional factor would appear to be operative in the former case. Nevertheless, atypical cases of dementia paralytica are not few, and in these it does not seem possible, whether by clinical, serological, anatomical, or histological means, to differentiate the condition from diffuse cerebral lues.

Neuropathic Inheritance in General Paralysis.

Those of us who have reached a certain age can recall that as students we were taught that this disease occurred in persons in whom as a rule no neuropathic inheritance could be found. Not only had their own lives been usually exemplary, with the possible exception of lapses in a remote youth, but they came from a sound stock. Naecke,[15] however, in numerous publications based upon most painstaking and prolonged investigations, has shown that hereditary predisposition to nervous disease is very considerable in dementia paralytica, scarcely less so than in other kinds of insanity, and that such certainly exists in 50 per cent. of cases. Schroeder[16] finds neuropathic inheritance, and evidence of neuropathic disposition in the patient himself, in 77·8 per cent. of cases. He quotes Fornaca, Koller, Soukhanoff, and Gannouchkine as giving figures from 70 per cent. to 75 per cent., and several writers give over 50 per cent. The observation of Schroeder, as to evidence furnished by the patient himself, points to the importance of seeking for evidence of defective development, as furnished by a study of the so-called "stigmata of degeneration," in the adult insane. In a paper published in 1899[17] I dwelt upon this subject, and submitted the scheme of examination I had been following; but in carrying out such inquiry we are met with the difficulty of obtaining control observations upon normal individuals of the same age-periods, social class, and district as the patients. Such controls would require to be carried out with the dead as well as the living subject, for there are of course anomalies of formation of internal as well as of external organs (internal and external stigmata). The above are no light hindrances. Observers are exceedingly few who have grappled with this difficulty; pre-eminent amongst them is Naecke. He asserts that external and internal stigmata are more frequent, grave, and widespread in general paralytics than in normal persons; he finds that in the former, in so far as the brain is concerned, microgyria, undersized frontal convolutions (especially), and the rarer variations or anomalies of the gyri and sulci, which especially indicate arrest of development, appear much oftener than in normal persons. The general paralytic's brain he regards as deficient *ab ovo*. Naecke quotes Vogt, who refers to observations by Roudonie, of Florence, from which it appears that there is in the juvenile general paralytics examined by him a cerebral cortex which in various details is immature (embryonal layer-formation, imperfect cells, anomalies of the medullated substance, &c.). Neuropsychopathic inheritance in dementia paralytica is regarded by Junius and Arndt[18] as the next most important factor to syphilis. They, too, place its incidence at 50 per cent. at least. In order to gauge correctly the importance of this factor we should know the incidence of neuropathic inheritance in cases of acquired syphilis in persons of the same age-periods, class, conditions of life, &c., who have not become general paralytics. Mattauschek and Pilcz,[19] in their interesting contribution to the percentage-incidence of dementia paralytica in 4134 cases of syphilis amongst army officers, found that only 4·7 per cent. developed the former condition, a result which bears out by actual inquiry the general belief as to the rarity of dementia paralytica amongst syphilitics. The question of neuropathic inheritance was not the subject of inquiry; it is, however, surely very improbable that marked neuropathic inheritance was lacking in the 95·3 per cent. of these syphilitics who did not develop general paralysis. Further figures bearing upon the question of the incidence of dementia paralytica in syphilitics are given by O. Fischer[20] (1913); thus, figures from Mattlies, 1–2 per cent. of syphilitics; from Pick and Bandler, 7 per cent., or 1·3 per cent. of 2066 cases, the former if men alone are considered, and tabes is in these figures included with general paralysis.

Comparison of Sleeping Sickness and General Paralysis.

The fact that syphilis preceded general paralysis having been established, it was highly suggestive when attention was drawn to the fact that sleeping sickness—a condition having a remarkable clinical and pathological likeness to general paralysis—followed upon trypanosomiasis, a disease with points of resemblance to syphilis, as is well brought out by Browning and McKenzie.[21] According to Schaudinn the spirochæta pallida stands near the trypanosome in the protozoal group. It is to be noted that trypanosomiasis does not lead to sleeping sickness in all cases by any means; I do not know in what proportion the sequence occurs, but the point is of interest by analogy with the parallel circumstance in regard to syphilis and dementia paralytica. Spielmeyer[22] states that only a very small percentage of experimental animals infected with T. gambiense shows a condition comparable to sleeping sickness. The curability of trypanosome fever and of syphilis contrasts with the incurability, at present, of sleeping sickness (the dementia of trypanosomiasis) and dementia paralytica. A brief reference to the clinical and histopathological resemblances between the last-mentioned states may be permitted. These are well brought out by Vix[23] and by Spielmeyer and Martin.[24] The former, examining patients in the sleeping sickness camps of German East Africa, found that 55 out of 70 presented marked mental symptoms, amongst which he mentions epileptiform seizures, closely resembling those of general paralysis, exalted delusions, with, later, apathy and progressive dementia; on the physical side he observed paresis, tremors (including tongue-tremors), articulatory disturbance, ataxia, contractures, wasting, exaggerated knee-jerks, and Romberg's sign. Most interesting of all, stationary states and remissions occurred in some of these cases. A distinction from general paralysis is that the pupillary reaction is usually intact. In respect to morbid anatomy, the following were among the conditions which resemble those of dementia paralytica: œdema and cloudiness of the pia, pachymeningitis hæmorrhagica, adhesions of the pia to the cortex, granularity of the ventricular ependyma, vascularity, with new vessel formation, perivascular infiltration with lymphocytes and plasma cells, rod cells, morbid changes in the nerve cells and neuroglia. Dogs infected with trypanosomes by Spielmeyer showed lymphocytosis of the cerebro-spinal fluid and increase of protein.

In marked contradistinction to the infrequency with which the treponema is still found in dementia paralytica is the frequency with which the trypanosome was found by Vix in sleeping sickness (65 out of 70 cases, in the blood or cerebro-spinal fluid). Another distinction is that the proclivity of the frontal lobes to suffer in the former disease is not noticeable in the latter. The trypanosomiasis recently described as frequent in Brazil, otherwise known as Chagas' disease, and due to the T. Cruzi (which is found in all regions of the brain in cases which run a chronic course and become demented) appears likewise to result sometimes in a condition resembling dementia paralytica.

Evidence of Toxic Process in Dementia Paralytica.

Cases of pellagra are on record[25] in which the psychical symptoms and neurological signs (reflexes, pupillary condition, speech) have resembled those of dementia paralytica, but the morbid anatomy of the brain was not inquired into. But before the evidence of antecedent syphilis was available, and long before the points of resemblance between sleeping sickness and dementia paralytica were known of, one should rather say long before the former disease began to be studied, the clinical and pathological evidence of the toxic nature of the morbid process in dementia paralytica was recognised as strong. From the clinical standpoint there are the exacerbations and remissions, very suggestive of recrudescence and quiescence of a toxic process; the variations of temperature, of unknown causation, and only found when the temperature is taken several times daily over long periods; and the seizures. The latter are comparable to those observed in uræmia and eclampsia. There is the polynucleosis of the blood in connexion with exacerbations, and some would add that of the cerebro-spinal fluid, with which points I shall have occasion to deal in another lecture. As regards morbid histology, the well-known changes in the walls of the cerebro-spinal vessels, in the perivascular and interstitial tissues of the central nervous system, are suggestive of a toxic process. But these changes, including infiltration of these tissues with lymphocytes and plasma cells, are not limited to the nervous system. The workers who have examined extra-nervous organs are not many; I have not done so, but undoubtedly such work has been recorded in respect to individual organs from time to time. A complete anatomical examination is on record by Catola[26] in respect of seven cases of dementia paralytica, persons who had had syphilis and had died from seizures or cachexia. There were found in the viscera (especially the liver) vascular and perivascular changes (lymphatic infiltration, plasma cells) and parenchymatous degeneration resembling the changes in the nervous centres.

Spirochætes in the Brain Cortex in Dementia Paralytica.

Our knowledge may be summarised thus in regard to the demonstration in sections and films of the brain cortex.

Noguchi's statistics,[27] as published up to July, 1913, dealt with 200 cases; the organisms were found in nearly 25 per cent. in sections. Marinesco and Minea[28] found them (apparently in sections) in 1 case out of 26—nearly 4 per cent.; Levaditi, Marie, Bankowski,[29] in sections, in 3 out of 32—10 per cent. By the fresh film method of Fontana-Tribondeau (silver impregnation, after fixing and mordanting), Loeffler's fresh method, and dark-ground illumination they found the organism in 8 out of 9 cases—88·8 per cent. It is to be noted that the last-mentioned authors obtained these satisfactory results in cases which died in from 1 to 14 months after the diagnosis of the malady—that is, in rapidly progressing cases; furthermore, 8 of the 9 died from seizures. In Noguchi's original series rather more than one-half of the cases averaged only 17 months in duration. In the case figured by Uhlenhuth and Melzer, in their "Atlas of Experimental Syphilis in Rabbits," a syphiloma was produced in the testicle by inoculation of brain-material from a particularly early case of general paralysis. Scholberg and Goodall examined films prepared from the cortex of the frontal lobe on the morning upon which death occurred in 8 cases, all of them examples of long-standing disease (dementia paralytica), the dark-ground, Indian ink, and Fontana-Tribondeau methods being used. In none were undoubted spirochætes found, although doubtful instances occurred in two of the cases. From the foregoing it appears that statements still vary considerably as to the frequency with which the spirochæte has been demonstrated in the cortex cerebri in dementia paralytica.

Inoculation Experiments.

The following few results are recorded. Noguchi: fresh brain-emulsion of general paralysis of the insane into testicles of 42 rabbits; sclerosis of testis, with T. pallid in 2 (92 and 105 days). But von Jauregg[30] speaks of positive results obtained by Noguchi in 22 out of 36 rabbits so injected, after from 97 to 102 days. Berger[31]: emulsion made from brain-substance obtained by puncturing the frontal lobes, inoculated into rabbit's testicles; 3 of 20 rabbits showed spirochætes in the testicle. Forster and Tomasczewski[32]: the same procedure (the living organisms demonstrated in the brain-substance in 40 per cent. of the cases punctured) failed to inoculate 39 rabbits and 5 apes, although many of the animals had been under observation four months. Greefs[33]: a positive result, inoculating rabbit's testicle with the blood of a general paralytic. Marie, Levaditi, Danylewsky[34] the same; treponema found after 190 days. Uhlenhuth and Melzer[35]: in one case organisms found in testicle (syphiloma) inoculated with brain-emulsion, but only negative results when blood and cerebro-spinal fluid used. Scholberg and Goodall: the testes of 8 rabbits inoculated with emulsion of living spirochætes from primary sores and condylomata. Death in 25 to 45 days. The organisms found in one case only in abundance after 40 days. A portion of the testicle from this was incubated anaerobically, as described below, upon serum-water. No spirochætes found after 35 days.

We also inoculated suspension of the frontal cortex from four general paralytics (long-standing cases), made in from two to seven hours of death, into the testes of 17 rabbits. Of these, four are still alive three and three and a half months after. The testes exhibit nothing abnormal, but two of the rabbits are in a reduced condition, are desquamating and losing fur freely, and have lost weight considerably. The others died in from 66 to 90 days, for reasons unknown. No spirochætes were found in these testes by the fresh film methods. Portions of these testes were placed in serum water, 1 : 3, prepared from a general paralytic's serum; this culture-medium was incubated under strictly anaerobic conditions in vacuum-tubes, or tubes from which all air had been removed and replaced by hydrogen (which gas had previously in both cases been passed through the culture-medium). Some tubes showed organisms, not spirochætes; others remain sterile at the end of 23 days and 86 days. On four occasions we dealt with 50 c.c. of cerebro-spinal fluid collected from several cases of dementia paralytica, the fluid being centrifugalised at 3500 revolutions per minute for three-quarters of an hour to one hour. The deposit was examined by the film-methods, and culture tubes of rabbit's testicle + dilute serum from a general paralytic were inoculated with it; the tubes were incubated under the same strict anaerobic precautions as above described. These results were negative.

From the foregoing it appears that the cultivation of the spirochæte from the brain of general paralytics, whether in living tissues or in culture-media prepared in the most approved manner, is an extremely difficult matter. The methods at present available are very uncertain in respect to results obtained. The negative results of Forster and Tomasczewski are particularly striking, for spirochætes were proved to be abundant and living in the brain-tissue, and had they been dealing with spirochætes from a primary syphilitic lesion they would doubtless have obtained some positive results out of such a large number of inoculations.

Changes in the nervous system as a result of experimental inoculation with material containing spirochæta pallida.—Although many more investigations are required, with parallel observations upon other tissues, it is obvious from those recorded by Jakob and Weygandt[36] and a few others that the entire nervous system is involved in changes of an inflammatory nature in consequence of inoculation of the spirochæte; the morbid process involving primarily the membranes and blood-vessels, with production of inflammatory foci, suggestive of gummata, of abundance of lymphocytes, plasma- and rod-cells, with glia-proliferation, and the like conditions, such as we are familiar with in sections of the general paralytic's brain.

Diphtheroid Organs.

There are bacteria found in the tissues of general paralytics which it is easy to dismiss as merely capable of inducing secondary inflammation, but I do not think we as yet are sufficiently acquainted with them to assert as much as this. Whilst unable to follow Ford Robertson in his views as to the causative rôle in dementia paralytica of certain "diphtheroid" organisms described by him, I think it desirable that his results should be borne in mind, and not unlikely that the record of results obtained by the study of other bacteria will accrue to be collated with his. The diphtheroid organisms described by Ford Robertson[37] have been shown by him in large numbers, and associated with inflammatory changes of the parts involved, invading the walls of the respiratory (including the naso-pharyngeal), alimentary, and genito-urinary tracts, in the foci of catarrhal pneumonia which occur in cases dying in "congestive" seizures, in the walls of the cerebral vessels, in the perineural sheath of the trigeminus, in the pia-arachnoid, in the blood, and the centrifugalised deposit of the cerebro-spinal fluid, in the urine—in all these fluids especially after seizures. They invade the lymphatics of the parts involved. The mucosa of the tracts involved and the subjacent tissues present evidence of chronic inflammation. The bacilli have been cultivated from the blood, urine, and cerebro-spinal fluid. Rats and a goat inoculated with them from a case of general paralysis developed paretic symptoms, and histologically lesions closely resembling those of early general paralysis were found.

At this point I would refer to an interesting statement of Cerletti,[38] made at the Fourteenth Congress of the Società Freniatrica Italiana, and published last year, to the effect that in connexion with "cimurro" (glanders) in dogs, months after recovery from the catarrhal infection a demented state slowly supervenes, with ultimate cachexia and death. It appears that some veterinary surgeons regard this condition as the same as dementia paralytica. In it Cerletti has found a chronic encephalitis with diffuse lymphocytic and plasma-cell infiltration; and the cortical lesions he considers very like those of dementia paralytica.

O'Brien[39] found an identical bacillus to Ford Robertson's in five cases of dementia paralytica, during seizures, in blood from a vein, and in 70 per cent. of 62 cases in the cerebro-spinal fluid; whereas the result was negative in 30 non-general paralytics. In 11 of 14 cases large numbers of the bacillus were found in the stomach-wash after 24 hours' fasting. Characteristic symptoms and histological changes in the cerebral cortex are described in rats, dogs, and goats inoculated with the organism. Flashman and Latham,[40] repeating the experiments of Ford Robertson and Shennan, fed 15 rats on diphtheroids from a case of general paralysis. They describe pronounced inflammatory changes in the brains of these animals. Whilst it is claimed that changes typical of dementia paralytica can be produced in the cerebrum by this feeding process carried out over a long period, the changes described by Flashman and Latham are such as might be induced by various toxic agents; thus, by other organisms as well as those in question. Complement-fixation tests with the diphtheroids as antigen are described by Lind[41]; the results were negative in 45 sera and 34 cerebro-spinal fluids. Similar tests carried out by Eyman and O'Brien[42] gave a positive Wassermann reaction in 36 of 42, or 90 per cent. Candler[43] sought to test the results of Ford Robertson, and his contribution is important, covering a large number of cases of dementia paralytica and of other kinds of insanity, the blood, cerebro-spinal fluid, and urine, and the respiratory, alimentary, and urinary tracts being examined. The total percentage-incidence of diphtheroids in the former was 12·2, in the latter 8·4. No diphtheroids were found in the blood (27 cases, many times examined, including examinations during and after seizures), nor in the cerebro-spinal fluid (9 cases), nor in sections of the brain, although Ford Robertson describes them in such sections. Unlike the other observers quoted, Candler found no histological changes resembling those of dementia paralytica in the brains of rats fed or inoculated with these organisms. A. Marie[44] has also failed to find the diphtheroids in the nervous system or the body-fluids in this disease, and no evidence was elicited by him in favour of their specificity by the agglutination test or by the opsonic index method. Marr failed to cultivate any organisms from the cerebro-spinal fluid in 53 cases of dementia paralytica. The same was the experience of Parkinson[45] in each of 15 general paralytics. Barton White,[46] working in the laboratory of the Cardiff Mental Hospital, examined the blood freshly drawn from a vein in 11 pronounced cases of the disease under strict aseptic precautions, using as media broth in quantity, in Pasteur flasks, and nasgar: the media remained sterile in every case. Other observers have had the same negative results in culture experiments or have failed to find bacteria; and there can be no doubt that in dementia paralytica organisms, whether spirochætes or bacilli (I do not refer to cocci found in terminal conditions), are very difficult to find, and still more difficult to cultivate.

The Question of Lues Nervosa.

Since the demonstration of the spirochæte in the brain of general paralytics attention has been mainly focussed upon a particular problem in the pathology of the disease—namely, its relations to syphilis. The rarity of the disease in syphilitics, the mild nature of the antecedent syphilis in general paralytics, the clinical and pathological peculiarities of general paralysis, the difficulties surrounding the detection and culture of the spirochæte in general paralysis, the difficulty of inoculating animals with this organism as compared with the organism of ordinary syphilis, these and the like considerations have prompted the suggestion of a spirochæte with special affinity for the nervous system, the possibility, in other words, of a *lues nervosa*. The soil is often not a normal one, there being, as has been said above, evidence of neuropathic inheritance in a considerable proportion of general paralytics. Recently (1913), in an instructive article, O. Fischer[47] has dealt with the evidence in favour of a lues nervosa; as, for example, evidence furnished by conjugal general paralysis, by cases in which two or more persons have acquired general paralysis or tabes after infection from a common source (a most extraordinary instance of development of general paralysis by individuals infected from a common source is furnished by Moerchen[48]; no less than 11 men got the disease after infection from the same syphilitic female); by cases of women who have acquired these conditions, rather than ordinary lues, after infection by men suffering from them; and evidence to the effect that of two sets of individuals, one infected by luetics who subsequently got dementia paralytica and the other by luetics who did not, the former are more liable to get a so-called "metalues." Such considerations open up a vista of prolonged and patient inquiry.

A Therapeutic Measure.

At this point it is convenient to refer to a therapeutic measure which has been found of practical utility in the treatment of general paralytics of recent years, and which is founded upon exact investigation—I refer to the administration of hexamethylenetetramine. This drug was probably in the first instance employed in these cases upon the clinical observation that the urine of general paralytics was peculiarly liable to decomposition. I have found little or no reference to the use of the drug in dementia paralytica in the literature, but am aware from communications from colleagues that good effects have been observed as a result of such use, and my experience coincides with theirs. More time is required ere definite statistical statements can be made in respect to this matter, but the impression of certain of us who have used the drug in ordinary institution-cases of dementia paralytica is to the effect that it tends to prolong the life of the patient by maintaining him for a longer period in a stationary state or in a remission. As to whether the drug diminishes the number of convulsive seizures further evidence is needed. The only figures with which I am acquainted are those of Baird,[49] which go to show that it does. Recently Barton White,[50] in a research carried out at the laboratory of the Cardiff Mental Hospital, found that the urine showed various micro-organisms in each of 10 general paralytics, whereas in 10 controls of other forms of mental disorder they occurred in only 3; further, that the urine became sterile after a course of hexamethylenetetramine, with formation of formaldehyde (as demonstrated in the urine), and remained so for periods extending to four weeks; so that one concludes that the urine can be maintained in a sterile condition by the regular administration of this drug. Urotropin is reported to appear to some extent in the cerebro-spinal fluid when taken by the mouth. Possibly it acts beneficially by warding off secondary infections. Further observation and inquiry are needed, and meantime the administration of the drug referred to would appear proper in early cases, such as are not seen in institutions.

MICRO-ORGANISMS AND TOXINS IN CONNEXION WITH MENTAL DISEASES.

The evidence furnished by the morbid histology of the brain in the acute and recent psychoses is not in favour of anything approaching a virulent toxæmia, with the doubtful exception of the condition known as "acute delirium," or "acute delirious mania"; neither does clinical evidence point to such, with the same possible exception. The temperature-pulse-respiration chart in cases of acute and recent mental disorders shows very little evidence of febrile reaction. Toxins, if any, must be of a low degree of virulence. We know, however, that various drugs which are incapable of producing the bodily disturbance or reaction which accompanies an attack of one of the specific fevers, and from this point of view are not virulent, are nevertheless able to produce very definite mental disturbance. Whilst morbid histology affords practically no evidence of acute toxæmia in the psychoses, the changes found are quite compatible with the operation of a toxin of a milder kind. This is true, apart from dementia paralytica, for acute delirium, acute mania or melancholia, the psychoses of exhaustion. Cases of the disorders grouped under the name "dementia præcox" do not, for all practical purposes, come to necropsy in the acute and recent phase, so that, unfortunately, we have no sufficient information in respect to these. The examination of the blood in the acute and recent psychoses with the usual aerobic methods, upon the usual culture media, gives negative results. Sewell and McDowall[51] investigated the blood for organisms in 50 cases of insanity, of which 12 were cases of mania, 27 of melancholia, and 11 of various chronic psychoses; they were only able to record one positive result, but in this case the presence of a coccus was associated with intercurrent septicæmia. A research by Gay and Southard is worth mention, as it embraced 100 cases of mental disease, although observations were made on the cadaver; the bodies, however, had been kept at freezing point. They obtained cultures in no less than 59 per cent. in the case of the blood and 72 per cent. in that of the cerebro-spinal fluid; colonies upon plates were also more abundant in the latter case. It is to be observed, however, that the cases examined were chiefly in a chronic condition of mental disorder, and had succumbed to exhaustion. The organisms found were of the most varied description, chiefly micrococci and bacillus coli, the most curious feature being the frequent association of bacillus coli with evidence of fatty degeneration of the spinal cord, and of generalised softening of the brain, so that the authors believe that a definite relationship must be assumed to exist between bacillus coli and its toxins and nerve-fibre degeneration.

Of all mental disorders the condition known as "acute delirium," or "acute delirious mania," is that in which we should most expect to find evidence of bacterial origin, on account of the acuteness of all the mental symptoms and the existence of grave bodily illness. The rarity of this condition has largely prevented its proper study; amongst the rate-supported insane, at any rate, it is extremely rare, and I can only remember to have seen two or three cases in my experience of 24 years, and one of these was at Bethlem Royal Hospital, which does not receive the rate-supported. In my student days at Bethlem the question was discussed, by Percy Smith especially, as to whether this condition was merely the gravest form of acute mania or a separate entity; and this question still remains unanswered. No significance is to be attached upon scientific grounds to any organism hitherto found in the circulation in this disease. The condition is seen in connexion with typhoid and other infectious disorders, and it would therefore appear that more than one toxic agent can produce it, unless, indeed, such acts merely as a predisposing cause. Kozowsky[52] in a recent communication upon the pathology of acute delirium, states that staphylococci, diplococci, and the influenza bacillus have all been found in cases of that disorder, and this is not surprising, seeing that the state follows upon diseases in which these organisms are causal agents. I am not aware of any record of animal inoculations in connexion with cases of acute delirium. The psychoses following upon specific fevers but rarely come to necropsy, so that we have no sufficient information as to the histological conditions present in the brain in such cases.

The Infection-Psychoses.

This brings me to the consideration of the psychoses due to infection- or intoxication-processes. By these we mean disorders of mind, which amount to more than mere transitory delirium, and which supervene in the course of, or follow upon, infectious fevers, or specific diseases attended with fever. These psychoses seem to me peculiarly worthy of study, for thereby we are likely to obtain an insight into the pathogenesis of similar disorders of mind which arise without any obvious cause other than a mere deterioration of health. The infection-psychoses, as they may for convenience be termed, are rarely seen in public institutions for the insane; in the first place, they are uncommon; in the second, they are mostly of brief duration. They are to be met with more frequently in the psychiatric cliniques of university towns on the continent, no doubt because the patients are readily transferred thither from the ordinary medical cliniques when they become troublesome—a proceeding involving no legal formalities—and they are also directly received into such with the minimum of trouble.

Amongst the specific fevers, typhoid yielded up to recent years the largest number of these cases, but of late years influenza has been a potent factor. Friedländer gives 1·5 to 2·5 per cent. as the number of cases of typhoid in which psychoses occur. Erysipelas affecting the head is probably the next most frequent cause; thereafter come malaria and pneumonia. Puerperal insanity, which belongs to the category of the infection-psychoses, is in a class by itself. These psychoses, whilst no doubt mainly appearing after the bodily illness has manifested itself, or at its close, may appear in the form of delirium or mania before there is any fever, and are then only ascribable to a toxin, and fairly comparable to a psychosis due to some drug, to a poisonous substance used in an industry, or to ptomaines. Furthermore, the mental disorder does not by any means necessarily go with high temperatures, even when it appears after the bodily illness has become definitely established. This is the first instructive lesson I draw from a study of the infection-psychoses; they illustrate (in common with insanity from drug-poisoning) the ability of a toxin to cause insanity. A second instructive fact is that there is no difference in the kind of symptoms by which one can distinguish the psychosis caused by one infection or intoxication from that caused by another. The brain reacts in common, limited, well-recognised ways, irrespective of the nature of the provocative disease, it reacts to toxins; from which it appears that different toxins are capable of producing the same effects upon the cerebral cortex.

These psychoses exemplify the most diverse clinical forms; thus, acute delirious mania, mania, melancholia, states resembling closely certain of those deemed characteristic of dementia præcox, others resembling those seen in insanity with epilepsy (e.g., states of agitation, post-epileptic stupor), acute confusional conditions, an exalted state resembling that seen in dementia paralytica, the syndrome of Korsákow—with its preliminary agitation and subsequent disorder of memory and attention-power; above all, they take the form of acute hallucinatory insanity. In the post-febrile period dementia of varying degree is shown. In short, if we exclude systematised delusional insanity, the above summary includes practically all the forms in which disease of the mind manifests itself. The specific fevers can reproduce them all, so that differential diagnosis from like mental disorders as ordinarily seen is for the time being practically impossible. The only essential difference is that in the symptomatic psychosis the disorder is commonly of shorter duration than in the so-called "endogenous" psychoses, although after typhoid and influenza varying degrees of mental defect may last for years. The above considerations naturally prompt the inquiry as to whether the forms of insanity we are accustomed to meet with, of unknown origin, are due also to toxins, exogenous or endogenous. A third point which is noticeable in connexion with the infection-psychoses is that one and the same provocative disease (toxin) produces different forms of mental disorder in different persons, which is presumably due to individual peculiarities.

A special reference seems desirable to the pseudo-general paralysis which occurs in connexion with some of the specific fevers, a point alluded to by Bonhoeffer[53] in his study of the symptomatic psychoses. As far as I am aware, the pupillary reflexes are never altered, but the typical mental symptoms are reproduced, and the speech is affected, although not typically, yet in such manner as to cause difficulty in diagnosis. The knee-jerks may be exaggerated. As the pupillary phenomena are not present in every case of true general paralysis it must have been practically impossible to diagnose the simulated from the real disease by the mere symptoms in days prior to the introduction of serological, chemical, and cytological tests in respect of the cerebro-spinal fluid. A further special reference may be made to the occurrence of symptoms indistinguishable from those given as characteristic of the katatonic variety of dementia præcox. There are the stupor, flexibilitas cerea, verbigeration, echolalia, and echopraxia, stereotypy, rhythmical movements, rigidity of attitude, grimacing, mimicking, tics, and negativism; in fact, there is the entire symptom-complex of this type of dementia præcox. Bonhoeffer has recently given some good descriptions of this condition following upon typhoid and pneumonia. A condition resembling katatonic stupor has been described[54] as developing in a case of pellagra; the patient apparently had a predisposition to mental disorder, as she had an attack of mania six years previously, before the pellagra showed itself. The infection-psychoses furnish instances in which a given symptom-complex is produced by more than one morbific agency, and therefore constitute an argument against specificity in causation of the various kinds of insanity. The abnormal constitution of the brain in individuals falling victims to mental disorder would seem to be of more importance than the exciting cause; the *irritabile* more important than the *irritans*.

Disorders of Metabolism in Insanity.

In the foregoing remarks I have dwelt upon matters histological and bacteriological. I have endeavoured to indicate how, in respect to the former branch of study, the interest of research workers in the domain of mental disorders showed undoubted signs of slackening some 15 to 20 years ago, so that there were those who said that no more good was to be derived from histological work. Yet a remarkable impetus was shortly to be given to such by the admirable work, with new methods, of Nissl and Alzheimer, to whose "Histologische und Histopathologische Arbeiten" we are so much indebted. I have endeavoured to indicate the passage of the attention of research workers through the domain of bacteriology. Here, again, the negative nature of the results obtained has been the cause of discouragement, but the improvement in technique and elaboration of methods —not yet taken advantage of in the laboratories of mental hospitals—will demand for this branch of work closer attention than ever, to say nothing of the necessity for the study of the problems of artificially-conferred immunity. Following the stream of tendency, interest has passed on to problems in the domains of physiology and chemistry. During the past six years a considerable number of publications has appeared concerned with metabolism-experiments in the insane, and chemical examinations of the brain, and especially of the excretions, have been carried out. It is regrettable that most of the work done in respect to metabolism and chemical research is of no value, owing to lack of training on the part of those who have carried it out. The study of metabolism in mental disorders is in its infancy; methods hitherto employed are inadequate to deal with the subject. The same is true of chemical methods. The most concordant results are in respect to epilepsy with insanity, dementia paralytica, dementia præcox, and manic-depressive insanity. But the changes observed up to the present are not pathognomonic. At some of the continental psychiatric clinics it is now feasible to prosecute research in metabolism and chemistry, and even in this country a start has been made by way of providing like facilities.

One of the most critical surveys of the present position as to our knowledge of metabolism in the insanities is by Allers,[55] of the Munich Psychiatric Clinique. To his survey I am indebted, as also to the criticisms of Dr. R. V. Stanford, research chemist at the Cardiff Mental Hospital. That psychical disturbances influence metabolism is but another way of saying that the body is influenced by the mind. It having been demonstrated in a given case of insanity that a disorder of metabolism is present, the question of cause and effect remains to be determined. One of the best instances of parallelism between disorder of mind and disorder of metabolism, and one of the readiest to suggest itself, is the occurrence of glycosuria in conditions of mental agitation, or agitation with depression, such as occur in different kinds of insanity. According to Allers the periods of excitement of general paralytics and epileptics are associated with an excretion of acetone-bodies. The origin of these is a matter of speculation. Then there is the phosphaturia connected with states of mental agitation. I fear that in such instances as these it is difficult to get beyond the unsatisfactory position of psycho-physical parallelism. More satisfactory is such a case as that described by Kauffmann[56] of typical "angst-psychose" and diabetes, in which the mental disorder was worse or better with the rise or fall of sugar in the urine. All carbohydrates were withdrawn, and the sugar fell to 3 per cent., 0·3 per cent., and 0 per cent. The psychosis disappeared with the sugar. And a like case, by Fornaca,[57] of manic-depressive insanity, excreting a very large amount of glucose about the time of the depression-phase. Antidiabetic treatment produced rapid improvement. In myxœdema, in which the physical change has its psychical counterpart, there is a general lowering of metabolism, as might be expected, since it is known that the thyroid gland has a general stimulating influence upon the exchanges. Magnus Levy showed that the metabolism in myxœdema is decidedly raised by the administration of thyroid gland. The production of energy in this disease, as represented in calories, is greatly below normal,[58] and von Bergmann states that a 50 per cent. increase in energy is brought about by administration of thyroid. And Bornstein, in the work I shall presently refer to, observes that the administration of thyroid causes an increase in oxidation in myxœdematous cases, as measured by the Zuntz-Geppert method of "short experiments." Improvement in the general health by thyroid treatment is accompanied by mental improvement. In such instances as the above one is justified in ascribing the mental to the metabolic disorder.

Thyroid Treatment.

At this point I may appropriately refer to the question of the treatment of certain cases of insanity by thyroid extract. For 20–24 years—I think that period is correct—this treatment has been in use, more or less; extolled by the few, faintly praised or rejected by the majority. It has been mainly used, I believe, in cases of stupor and stupor with melancholia, or cases of confusional insanity; in brief, cases which have certain features in common with myxœdematous cases. What we know of the $O-CO_2$ exchange in cases of dementia præcox (under which term cases of stupor are now included) justifies the use of a substance like thyroid, which promotes oxidation changes. I have employed it for many years in such cases, and candour compels me to admit that until the last two years the failures in my experience were more numerous than the successes. I now attribute at any rate many of those failures to the circumstance that I gave insufficient doses of thyroid. My recent experience entirely justifies those who have insisted upon large doses if any benefit is to follow. Thyroid I have found not only beneficial in acute stupor, or acute dementia, and "confusional" states, but also at a later stage of these conditions and of cases of recent melancholia, when the patient has improved to a certain point and there remained. In these the administration of thyroid has appeared to complete the process of recovery. Richter,[59] it is instructive to note, states in his work on metabolism and its diseases that it is especially when the metabolism is commencing to increase that thyroid gland acts well in simulating it. I shall now give briefly the details of the treatment of 11 cases of mental disorder by this method. These patients, in accordance with my practice, were kept in bed during the whole course of treatment, usually in the open air, upon liberal diet; and the temperature, pulse, and respiration were taken throughout twice daily. From Table I. (illustrating six of these cases which were discharged) it is seen that all had been mentally ill for several months before the thyroid treatment was started, which was in considerable measure unavoidable owing to the delay which occurred in sending them to the mental hospital. In this respect the method of treatment was at a disadvantage. The large total amount of thyroid given, the lengthy periods over which the treatment extended, the large maximum doses reached—these are features worthy of attention. The pulse-rate was affected in the direction of increase very consistently, as was to be expected, whereas the temperature and respiration were affected but slightly, or not at all. As to weight-changes, gain of weight during the treatment occurred in 2 of 11 cases; 1 showed no change; in all the others a loss was noted, as we should expect; but after cessation of treatment weight was rapidly regained, and in 8 instances there was ultimately a gain on the original weight.

TABLE I.—*Thyroid Administration in Mental Disorders.*

Case and diagnosis.	Duration of malady before treatment started.	Total thyroid given in grains, and in what period.	Maximum amount per diem in grains, and for how long.	Particulars of pulse-rate during treatment.	Particulars of respiration.	Particulars of temperature.	Weight changes.	Result.
A. E., aged 17. Dementia at puberty.	3–4 months	850. 5 weeks.	45. 4 days.	Notable and consistent +. Maximum + 40 beats per minute.	Not increased.	+ from subnormal to normal, or slightly over.	Gained 6 lb. Gained 1 st. one month after treatment.	Discharged recovered.
W. D., aged 27. Stupor after childbirth.	5–6 months.	1265. 6 weeks.	60. 3 days.	Consistent + to maximum + of 22 beats per minute.	,,	Occasional slight +, mostly subnormal.	No change. Gain of 4 lb. in a fortnight after treatment. No further gain.	,,
J. H., aged 28. Dementia.	8–9 months.	1435. 7 weeks.	55. 1 day.	Consistent +. Maximum + of 42 beats per minute.	Consistent + to maximum of 10 per minute.	Rises and falls, but often from 99° to 100°.	Lost 8 lb. Regained this in 14 days. Final gain 3 lb.	Discharged relieved.
J. O. T., aged 28. Dementia.	2¾ years.	1060. 6 weeks.	45. 6 days.	Consistent + throughout. Maximum + = 42 beats per minute.	Consistent + to maximum of 14 per minute.	Rises to 99°–100°. Also falls to below normal.	Lost first 4 lb. Regained 9 lb. in one month after treatment. Final loss of 6 lb.	Discharged recovered.
A. W., aged 16. Dementia at puberty.	4–5 months.	At least 580. 4–8 weeks.	38. 5 days.	Consistent +. Maximum + = 20 beats per minute.	Not increased.	Rises and falls (rises to 99°–100°).	Lost 2½ lb. Gradually gained, after treatment, to gain of 3 st. on original weight by discharge.	,,
A. M. B., aged 17. Dementia at puberty.	6 months.	1010. 5 weeks.	60. 3 days.	Consistent + to maximum + of 40 beats per minute.	,,	With few rises to 99°, remained subnormal.	Lost 6 lb. Regained, and final gain after treatment—6½ lb. (on original weight) end of one month.	,,

+ = Increase.

The results, it will be seen, were highly satisfactory, since no less than 6 patients of 11 left well; and all the others save one showed a definite improvement, and this one had been deranged for no less than three years when treatment was employed. I shall presently have to refer to such small amount of work as has been done upon the histology of the ductless glands in insanity, and would here merely observe that there is not as yet any justification from the standpoint of morbid anatomy for thyroid treatment in the cases which are placed in the group "dementia præcox," but in some cases of epilepsy there is, assuming, that is to say, that the morbid changes shown in the thyroid in these cases are primary and not secondary.

Upon this basis I have treated the following cases of epileptic insanity experimentally, with the result stated. Table II. shows that the number of fits were reduced by the thyroid treatment in 11 out of 12 cases, and in some the reduction was very marked. (See D. McG., W. B., T. H., M. H.) The patients were not on any other drug, but they were kept in bed on ordinary diet with, in some cases, extras, such as milk and egg. A reduction of weight is shown to have occurred in all except one. The observations as to the pulse, respiration, and temperature made in connexion with the first series of cases apply also to this series. On the basis of these results I kept certain of these patients upon 5 grains of thyroid daily for a prolonged period; the patients were up as usual and on their usual diet. Table III. shows the results.

TABLE II.—*Thyroid Administration in Epilepsy with Insanity.*

Case.	Monthly average number of fits for three months before treatment.	Number of fits in a period before treatment.	Number of fits in same period during treatment.	Weight on commencing.	Weight on terminating.	Total amount of thyroid in grains during period of treatment.	Maximum amount in grains per diem, and for how long.

It is seen that a substantial reduction in the number of fits occurred in many of these cases, amounting in some to from 52 per cent. to 65 per cent., as a result of a small daily dose of thyroid. It remains to be seen whether the effects of the drug are maintained for such a period as a year. No ill-effects were observed. This action of thyroid gland is of considerable theoretical interest, and the results obtained naturally prompt the inquiry whether benefit would follow upon the administration of other ductless glands in like cases or in cases where thyroid failed. I find that Cerf and Vassale [60] have reported several cases of epilepsy which were clearly improved by thyroid treatment, but in other cases no benefit accrued. The observations referred to above afford some grounds for the view that the function of the thyroid gland is impaired in some cases of so-called "dementia præcox" and of epilepsy, with and without insanity. These cases appear suitable for the application of the Abderhalden ferment test, to the employment of which in mental disorders I shall later refer, and also for testing on the principle of complement deviation.

Metabolism in Epilepsy.

The work of Rohde [61] is cited by Allers as particularly exact and critical. He finds in severe cases a disturbance in nitrogen metabolism, there being a retention of nitrogen, which reaches its maximum immediately before the fit. The pre-paroxysmal stage is also marked by the appearance of an increased quantity of ether-soluble acids. The significance of this expression is dubious and it requires explanation. The retention of N would appear to be the characteristic of the fit-free stage, but it is not peculiar to epilepsy, for a similar condition has been described in connexion with the katatonic phase of dementia præcox and in dementia paralytica. After the epileptic seizure there is an increased excretion of N, which reaches a maximum at the close of a series of fits, and after the *status* there is a negative balance. Uric and phosphoric acids are also excreted in increased amounts and also lactic acid; the last is probably due to muscular contractions and asphyxia. Guidi,[62] from his researches into the pathogenesis of epilepsy, also describes a profound alteration in nitrogenous metabolism.

The above reference to the treatment of epilepsy prompts me to bring forward Table IV., which deals with the results of treatment by means of diet and small doses of bromide. The patients in question were kept on the following diet:—Breakfast: bread, 6 oz.; margarine, ½ oz.; tea, 1 pint. Dinner: potatoes, 12 oz.; milk, ½ pint; cheese, 1 oz. Tea: as breakfast. On Sundays only was meat allowed—7 oz. Salt on the table at dinner was replaced by 10 grains of sodium bromide dusted over the food. This was all the bromide received—a very small amount for insane epileptics. None of these patients was upon drug treatment prior to the issue of special diet. The general health was not adversely affected by the diet. Whilst five patients lost from 2 lb. to 6 lb. in weight at the end of the period of treatment seven gained from 1 lb. to 11 lb.; one showed no change.

Metabolism in Dementia Paralytica.

The study of metabolism in this disease is rendered extremely laborious and uncertain owing to the restlessness of the patients and the difficulty of obtaining 24-hour specimens of the excreta. In 1908 Kauffmann[63] wrote a monograph embracing the study of a few cases, but the value of his laborious work is much diminished by reason of its unsystematic and diffuse nature. He brings out the point of the disturbance of the water balance; the balance is negative, the loss of water partly accounting for the enormous loss of weight in this disease. Other workers, as Allers (see below), refer to the great variations in the water balance. There are, further, great variations in weight not dependent upon food intake. The loss of weight is not counterbalanced by subcutaneous infusion of salt solution. The process of heat regulation is also disturbed. For the temporary febrile states which one observes in general paralytics, if the temperature is taken regularly every three or four hours, and for which there is no apparent cause, Kauffmann suggests, by way of explanation, the accumulation of intermediate products of metabolism. The fever thus produced brings about increased oxidation and so becomes extinguished. These febrile states have commonly been explained upon a theory of infection and not upon one of auto-intoxication. In dementia paralytica, and, in fact, in all psychoses leading to dementia, products of degeneration of nervous tissue (*abbau produkte*) are to be found in the glia cells, and cells of the adventitia of blood-vessels, in considerable, sometimes in enormous, amount. These have commonly been looked upon as of a fatty nature, but on insufficient evidence. It remains to be seen what they really are from a chemical standpoint and, by experiment, what noxious influence they may have. In passing I would observe that the rôle of the spider-cells of the glia in absorbing and transmitting the products of parenchymatous degeneration to the lymph-system of the brain has not been demonstrated for the first time within the last few years by the methods of Alzheimer, as one might conclude from a perusal of recent literature, but was exceedingly well demonstrated by Bevan Lewis at the West Riding Asylum, Wakefield, some 22 years ago. On the other hand, there is as yet no evidence that these cells have the phagocytic rôle which he ascribed to them. Kauffmann's work goes to show that in dementia paralytica great changes in metabolism alternate with periods of relatively normal metabolism, which correspond on the clinical side with remission.

Folin's[64] "Studies in Metabolism," dealing with the urine, still constitute probably the most complete experiments we have in the domain of insanity. He emphasises the extreme fluctuations —much greater than in normal persons on the same diet and under the same conditions—shown in the daily amounts of the urinary constituents in dementia paralytica. That great variations occur in the total quantity of urine is obvious when 24-hour amounts are collected. He notes the marked tendency towards lowness of the nitrogen-sulphur ratio, which Allers (see below) confirms; a correct interpretation is to be found in a disorder involving excessive destruction of protein in the body. Folin speaks of a "strong suggestion of metabolic disorder" in this disease, but goes no further than this. In other cases he examined, of non-general paralytics, illustrative of various insanities, chiefly manic-depressive and dementia præcox, Folin found also pronounced variations from standard values in the urine, but these could not be correlated with any specific mental condition. I do not see that any useful purpose is at present to be served by statements as to the presence in the serum, in increased amount, of "lecithin" in dementia paralytica and epilepsy—such statements as have been made by Bornstein[65] and by Peritz.[66] These statements are based upon assumptions which the present state of chemical knowledge does not appear to warrant. Competent chemical opinion (which I have referred to above) leads me to believe that the term "lecithin" is one to avoid; it appears to be a hypothetical term. "Ether-soluble phosphates" contain phosphorus which can be estimated, but to go further, and calculate from this the amount of a hypothetical substance ("lecithin"), seems to be no more than make-believe. Recently Allers[67] has published the results of a prolonged research in the metabolism of dementia paralytica, his chief conclusions being that endogenous protein-metabolism is increased, as evidenced by the negative nitrogen (and sulphur) balance, with uniform intake of nitrogen. Nevertheless, the metabolic changes are not carried out to their end stages; they are quantitatively greater but qualitatively deficient—incomplete. These definite metabolic changes, occurring at any rate in certain phases of the disease, are regarded as showing the existence of a general, not merely a cerebro-spinal, disorder. Before their significance for dementia paralytica can be estimated control experiments in other organic diseases of the nervous system are necessary, but these, as Allers points out, are as good as non-existent. It is highly significant that considerable metabolic disturbance may be present with but small loss in weight, for in persons prone to mental disorder slight losses in weight frequently go with a definite disturbance of the mental balance.

Metabolism in Dementia Præcox.

The katatonic form has been carefully investigated by Rosenfeld,[68] the four cases he worked with being in a stuporose state; they were upon a fixed diet and fed by tube. The positive result was that N was retained in considerable quantity in all cases, even in periods when insufficient food was taken and the body-weight sank. The nitrogen he believed to be in the form of available free protein, and for reasons he states. Pighini[69] obtained a like result but in the chronic phase of the disease (which is characterised by dementia, negativism, tics, and stereotypy), and phosphorus was also excreted in diminished quantity, whilst excretion of calcium and sulphur was increased. In the acute phase, or with exacerbations, characterised by motor restlessness, impulsiveness, and sensory excitement, the N-balance was negative, and sulphur and phosphorus (especially neutral sulphur) were excreted in increased quantity, which Pighini ascribes to increased nucleo-protein katabolism. In the final, chronic stage, characterised by dementia—instances of which so largely help to fill asylums—the chemical exchange is physiological, as one would expect. These results are confirmed, in respect to nitrogen and phosphorus, by Nizzi.[70] In the active phase of this disease, as in dementia paralytica, there are great variations in weight, not wholly dependent upon food-intake; the latter may be abundant and absorption good, and yet the patient loses weight. The work of Rosenfeld goes to show that these variations, as in dementia paralytica, are due largely to disturbance in the water balance.

Turning now to the researches of Bornstein[71] upon the respiratory exchange in the fasting condition, the muscles being completely at rest (the so-called "grund-umsatz"). This observer investigated 12 cases of the hebephrenic type of dementia præcox by the Zuntz-Geppert method, which permits of the collection for analysis of an average sample of the expired air obtained from a series of natural expirations. In the majority of these he found a marked diminution in oxidation, the O-CO_2 exchange amounting to only from 75 per cent. to 94 per cent. of the normal, as measured in calories. Although the latter figure is within physiological limits, Bornstein points out that it was only reached because the patients moved, and so vitiated the experiment.

Grafe,[72] in 18 cases of stupor occurring in different forms of mental disorder—such as the katatonic form of dementia præcox, dementia paralytica—found a definite lowering of metabolism, especially in the dementia præcox cases. The production of heat was diminished to 39 per cent. below normal. Apart from myxœdema, such an extreme reduction is believed to be very rare. In these cases there was no marked emaciation and no hypotonicity of muscle. And such reduction is, according to Grafe, not found in chronic under-nutrition. From the researches of Bornstein, Bornstein and Oven, and Grafe it follows that the exchange of energy, as estimated in calories, is very considerably diminished, and below the limit of physiological variation, in some cases of dementia præcox. The amplification of this work is to be desired, and the verification of Pighini's observation, as to the increased elimination of neutral sulphur in the active phase of dementia præcox. Koch and Mann,[73] examining the brain in nine cases of this condition, found a diminution in neutral sulphur, which was independent of the cause of death, a result which accords with the observations of Pighini. The brains of general paralytics did not show any marked change in the neutral sulphur content. It is interesting that a high percentage of neutral sulphur is stated to be eliminated in certain forms of intoxication, as by phosphorus, cyanide, chloroform, chloral; and also in diabetes and pernicious anæmia.

Extremely little experimental work has been done in the metabolism of manic-depressive insanity. Seige[74] found in three cases of melancholia a marked tendency to retention of nitrogen to a certain maximum point, upon attaining which a large quantity of nitrogen is suddenly excreted. With the retention there was several times observed marked emotional disturbance. The retention and excessive excretion of nitrogen in other psychoses also have been recorded above.

UNIVERSITY OF OXFORD.—Dr. Alexander George Gibson, Christ Church, has been appointed University lecturer in morbid anatomy.

A CASE OF LEPROSY TREATED WITH RADIUM AND DIATHERMY.

By C. E. IREDELL, M.D. Lond., M.R.C.P. Lond.,
SURGEON TO THE ACTINO-THERAPEUTIC DEPARTMENT, GUY'S HOSPITAL.

Cases of leprosy occurring in medical men are rare, and I believe that none so far has been described in which radium and diathermy have been used. The case here recorded is that of a medical man who was superintendent of a leper asylum from 1901 to 1908.

In 1910 the patient first noticed a sensation of pins and needles in his left arm. This sensation gradually increased, and in the month of September while shaving he noticed on his left arm some maculæ with fawn-coloured centres and dusky borders. He at once thought that he might be going through the preliminary stages of leprosy, and on making himself sweat profusely he noticed that there was a dry patch on the left wrist extending over the fourth and fifth metacarpal bones, the other side and the rest of his body being quite wet. He then went to Dr. F. M. Sandwith, who hoped he had psoriasis but thought it might be leprosy, and also to Dr. J. M. H. MacLeod, who, on finding that a test-tube of boiling water produced no sensation of heat in the left arm, considered that he was undoubtedly suffering from maculo-anæsthetic leprosy. Shortly after this a macule appeared on the right hip. His blood taken from the macule, when examined by the late Dr. H. R. Dean, contained no B. lepræ and gave a negative Wassermann reaction. Cramps in the flexor plantar muscles and twitchings of the muscles of the hands, especially of the left adductor pollicis, next appeared, and in June, 1911, the numbness of the left little and ring fingers became more marked and the maculæ had increased in size and number. On the right cheek there was a leprome of the size of a pea. By this time the patient was never absolutely free from pain in the ulnar nerve, which, however, did not prevent sleep. This increase of pain was largely due to bruising the nerve by falling on stepping stones. He could not tell the position of the little finger without looking at it, and there was a feeling of discomfort in the left axilla. Over the left trochanter femoris was a patch of the size of the palm of the hand, which was less sensitive than normal. In November of the same year he felt that the right ulnar nerve was showing signs of being affected. He was unable to approximate the little and ring fingers of the left hand, and the ridges of the pad of the little and ring fingers were becoming obliterated. In January, 1912, he began to take iodated chaulmoogra oil. A swelling appeared on the lower lip which was considered by Dr. Sandwith and Dr. MacLeod to be a leprome. In May the maculæ had almost cleared up, but the nervous symptoms remained the same. In April, 1913, he noticed blood-stained mucus in the nasal passages, but on examination no B. lepræ was found. This search for the bacillus in the nose has been repeated frequently, always with negative results. In September, 1913, the leprome in the lower lip began to fluctuate, and Dr. J. W. H. Eyre found the B. lepræ in the pus from it. In October an application of radium of 25 minutes was given to the leprome, and a fortnight later, after discharging freely, it healed up. Between November, 1913, and April, 1914, inclusive, six applications of 22½ mgm. of radium were given to the ulnar nerve. In January, 1914, he began to be troubled with abdominal symptoms, and in April last he wrote: "Four times since Jan. 3rd I have been in bed for three days at a time with pain in the abdomen shooting all along the large intestine from the epigastrium to the end of the sigmoid flexure. Some considerable constipation with difficulty in extruding the fæces unless by an aperient was present, and I sometimes vomited without any feeling of nausea. I took blue pill, Hunyadi Janos, &c., with little effect, and stayed in bed and had only milk puddings, &c. This day I had radium as usual, and then diathermy to arms and afterwards from the right hypochondrium to the left groin. The relief to my arm was marked, and the next day I passed a very copious solid motion, and this was repeated daily. I was also free from abdominal pain." On June 10th he wrote: "The radium seemed to relieve the pain in the arm, and certainly it broke down a leprome in the lip, so that now there is only a small, dry, hard sebaceous gland instead of a leprome bigger than a pea. On the other hand, I am under the impression that the diathermy gave me more relief. I am hoping that the atrophied muscles of the thumb are plumper and that the contraction of the little finger is less. I also notice that I now have only undulating contraction and movements of the fingers and no fibrillations."

In this case three facts are specially worthy of note: (1) that the patient is better in all respects than he was six months ago; (2) that his improvement began when diathermy was started; and (3) that he felt better directly after each treatment. The disease in his case has been characterised by (*a*) maculæ, (*b*) two lepromes, (*c*) neuritic affections, and (*d*) intestinal trouble.

(*a*) These were the symptoms of the first stage of the disease and passed off before treatment was begun.

(*b*) The leprome on the cheek disappeared spontaneously; that on the lip was not treated with diathermy, and therefore it cannot be said what the effect of diathermy would have been, but it certainly seemed to respond at once to radium treatment.

(*c*) The effect of diathermy on the patient's ulnar nerve was remarkable. For some time he had been in the habit of putting his arm in a hot bath in order to ease the pain. After holding two electrodes in his hands for 20 minutes' treatment the pain in the arm was far more relieved than it had been by the hot baths, and he found that he was able to move the little finger better than he did before. Some twinges of the left external peroneal nerve cleared up with one application.

(*d*) No less striking than the effect of the treatment on the nerves was the effect on the abdominal trouble. While the treatment was in progress peristalsis was distinctly perceptible to the patient, and in the course of the 24 hours following very copious evacuations followed, although no drug was used. This is in marked contrast to what had happened in the first three attacks, when it was found necessary to use aperients largely. Since April, when the treatment started, he has had five treatments at intervals of a few weeks, and on two occasions he has spent a week in town and had treatment daily with corresponding benefit.

Dr. W. H. Barber tells me that Professor Unna, of Hamburg, uses the cauterising action of the diathermy current in nodular leprosy with remarkably successful results. So far as I am aware, however, the use of the non-coagulating action of diathermy in leprosy has not been described. In post-mortem examinations on cases of nodular leprosy the abdominal organs, especially the liver and spleen, are very generally found to be infected with the B. lepræ. Presumably they are affected in most cases clinically, and therefore no treatment which neglects them can be considered satisfactory. Pathologically the infection of these organs is of the same nature as that of the nerves in cases of anæsthetic leprosy. If, therefore, the thickening of the nerves can be reduced and the nervous symptoms relieved it seems possible that relief of abdominal symptoms by the same treatment might be attended by a corresponding diminution of the visceral affection. The improvement in the patient has been so marked as to encourage a further trial of it, and the patient, who has seen these notes and consented to their publication, is so much impressed by the treatment that he is contemplating going abroad to try it on a series of cases.

Cumberland-terrace, N.W.

ON SOME CASES OF ANOMALOUS FEVER.

BY SEYMOUR TAYLOR, M.D. ABERD., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE WEST LONDON HOSPITAL.

DURING the past three years I have seen four cases which presented many features of great clinical interest and much difficulty in diagnosis. As these cases in their symptoms and duration were unlike any well-known fever in most respects, I have used the above nomenclature.

It would be tedious to narrate the symptoms of all these cases, as they each bore much similitude one to another, and it will be sufficient if I record one case only, the course and clinical events of which I observed and carefully noted. It is necessary to preface the following remarks by saying that all the patients were elderly, the youngest, a male, being 75 years of age, and the eldest 81 years of age. Three were males, one a female. Singularly enough, in each instance the illness occurred in the early months of the year—January, February, or March. Being at a loss, in each case, to ascertain the cause of the illness, I carefully examined the sanitary arrangements of the houses in which they dwelt, the kitchens and the culinary utensils in use also coming under my inspection. In two of my cases especially I found stew-pans and saucepans, especially the copper ones, in a very dirty and ill-kept condition; and I have ascertained since that in the two earlier cases a similar foul condition obtained in the cooking vessels. Old and incompetent, but trusted, servants, who put their cooking utensils aside after use without any attempt to cleanse them, were probably the guilty cause of the illness in each case, though I was not able completely to establish this suspicion. In each instance the course of the illness ran much on the same lines, and all happily ended in recovery. The following record of one case will therefore suffice.

The patient, aged 78, a man of means, was living in a large, gloomy house superintended by a housekeeper. He complained of no very definite symptoms, but merely a general feeling of illness and malaise. Beyond a slight quickening of the pulse (80) and a little rise in temperature (98·8° F.) I found no signs of any definite disease. The bowels were slightly constipated and the tongue was somewhat furred. I ordered a simple saline purgative and put him on a light diet. On Feb. 12th the temperature had risen to 100·2° and the pulse to 95. He complained of sore throat. A general redness of the fauces was all that could be seen. The tonsils certainly were inflamed also and somewhat more prominent than normal, but there was no sign of diphtheritic membrane and no follicular tonsillitis and no skin eruption. In addition to his medicine he was ordered a warm gargle of weak solution of permanganate of potash. Previously to this a swab from the fauces was taken, but careful bacteriological examination failed to reveal the presence of any micro-organisms other than those often associated with ordinary inflammatory affections of the mouth. In other words, he had no Klebs-Löffler bacilli, but only a small amount of cocci, not of the Fraenkel type, and no evidence of Pfeiffer's bacillus. The teeth and their sockets were in quite a healthy state, as he paid periodic visits to a competent dentist, and had only recently been under his care. On Feb. 14th the patient complained of pain and tenderness in his larynx, and he was aphonic, also slightly deaf. The laryngeal mirror revealed some congestion of the aryteno-epiglottic folds; but the vocal cords were intact, though the mucosa of the trachea was somewhat red and congested. He had much cough, and expectorated with some pain and distress a glairy tenacious mucus, such as is usually observed in the early stages of inflammatory mischief in the upper air passages. His temperature had risen to 102·4° and his pulse to over 100. On Feb. 15th, the fifth day of his illness, the temperature still showed an upward curve, being 104°, though his pulse had only risen to 100. Auscultation of his chest revealed signs of rather extensive and general bronchitis, and the bases of the lungs were engorged. The tongue was dry, slightly fissured, and coated with heavy brownish fur. The face was flushed; he had sneezings and a profuse nasal discharge, which, however, was not offensive. The urine was entirely free from albumin and sugar. Towards the evening he became delirious and obstinate, and only with difficulty was kept in bed.

I prescribed with subsequent good results 1/6th grain of morphia, and it gave him some hours' rest and sleep. On Feb. 16th the patient complained of hiccough. He still had some mental obfuscation. The abdomen was distended. He had slight diarrhœa—three liquid stools during the daytime—but they were dark in colour, and not characteristic of typhoid fever, though extremely offensive. The patient had suddenly become very deaf, and the nasal discharge was muco-purulent. No spots were to be found on any part of the trunk; the spleen could not be felt, and there was no tenderness in the right iliac fossa.

As the temperature had now been steadily rising for six days and abdominal signs having become manifest, I had a "Grünbaum-Durham" (Widal) test examination of the blood made by a competent observer. The typhoid reaction was negative. I may here remark that this examination was repeated eight days later, with the same result. During the next week the progress of the illness was much the same. He continued to be delirious during the day time, and this symptom was aggravated during the night, entailing the constant care and attention of two nurses. Diarrhœa, with some attendant flatus, continued; the abdomen was still distended, but after careful and repeated examination for any rose-coloured spots none were ever discovered. Nor was the spleen enlarged, or if it were it was not sufficiently so to afford evidence thereof to palpation or percussion. He still continued to have dyspnœa and cough, and also expectorated a large quantity of tenacious mucus which was occasionally streaked, but not intimately mixed with, or stained by, blood as it is in true pneumonia. His face and lips were free from any signs of herpes.

Still the temperature curve suggested enteric fever, and his general condition certainly was that which is known as the "typhoid state." Further, a similarity to enteric fever was seen in the subsequent curve, which having remained at about 104° for two or three days gradually began to fall, until about Feb. 24th, or 14 days after the beginning of his illness, the downward line became very marked, and the thermometer registered 98·4° on Feb. 27th, the seventeenth day of his illness. When the chart was made out it was seen that the curve of the temperature was a typical "brick arch" curve, a gradual rise to a rounded top, and followed by a slightly more abrupt line of fall to the normal. But the fever had only lasted 17 days. The lung signs gradually cleared; diarrhœa ceased; the distressing tympanites and hiccough subsided, and his recovery was steady and uninterrupted. Convalescence was not marked by any untoward incident, and on the twenty-third day of his illness he was allowed, after much persuasion on his part, to sit up in his chair.

What was the true nature of this attack? What infectious disease did he, and the other similar patients, suffer from? Was it an abortive attack of typhoid fever?

Against this it may be urged that an illness quite similar in course, duration, and symptoms occurred in the spring of different years, and attacked three other elderly persons.

Now I would point out that typhoid fever in senile subjects is very rare, though not unknown. Also I would repeat that in none of the patients were any rose-coloured spots found; in all the serum reaction of typhoid fever was negative; the stools were not characteristic of that disease; the spleen was in no patient found to be enlarged; the duration of the fever was only 17 days (the shortest) or 19 days (the longest), and the distension of the abdomen was chiefly due to distension of the colon.

It can scarcely be admitted that the attack in each patient was a form of pneumonia due to some micro-organism other than Fraenkel's, though I am convinced that pneumonia may be produced by different varieties of cocci and other septic germs; and in addition I would remind my readers that ulceration of the large intestine, attended by meteorism, is not infrequent in ordinary pneumonia. On the other hand, it will be seen that the fall in the temperature was gradual and not abrupt. Again, the signs characteristic of pneumonia—viz., lividity, rusty spit, and herpes on some part of the face—were absent. It may be suggested that the attacks were really influenza, since they occurred in the spring or late winter, and that the symptoms were protean in each case; but there were no typical pains in the back and loins, nor in the eyeballs, nor in the lower thirds of the extensor surface of the thighs.

The clinical problem is therefore a difficult one, and I am inclined to fall back on the diagnosis that each patient suffered from a septic fever, probably brought about by food prepared in dirty utensils which contained some minute organism, possibly a coccus, which exerted a widespread infection, involving not only the nasopharynx and the buccal cavities, but also the Eustachian tubes which open into the former. Thence the infection extended down the respiratory tract, as well as to the gastro-intestinal canal, with the result that the patients had symptoms which might easily be mistaken for typhoid fever or for pneumonia, and the probable cause and nature of the illness overlooked.

PS.—Since the above was written Dr. Herbert A. Smith has recorded in the *West London Medical Journal* of November, 1914, a case somewhat similar to the above. But the attack only lasted eight days, and in this instance the diagnosis of influenza was probably correct.

Seymour-street, W.

EXETER CITY ASYLUM.—Dr. G. N. Bartlett was, at a special meeting of the committee of this institution, appointed medical superintendent. Dr. Bartlett had been previously at Bexley Asylum, and is at present assistant medical officer of the London County Asylum at Horton, Epsom. The salary of the post is £500 increasing to £600 per annum, and, as recently mentioned in THE LANCET, the medical superintendent will be allowed to act as a consultant upon mental cases occurring in the city of Exeter.

GLYCERINE IN BROMIDROSIS,

WITH A NOTE ON MILITARY NEEDS.

BY T. H. C. BENIANS, F.R.C.S. ENG.,
PATHOLOGIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.

Bromidrosis is a condition of offensive sweating, usually limited to the soles of the feet. It occurs most frequently, although not entirely, during the hot months of the year, and it is well known to be highly resistant to treatment. Associated with the condition in severe cases there is usually marked tenderness of the soles, and abrasions and blisters readily form. The condition is attributed to the results of bacterial decomposition of the sweat. The whole of the influences at work in the causation of bromidrosis are not altogether clear; numerous and various bacteria are present in all cases, and probably some essential constitutional factor is in operation in addition to the bacterial infection.

Of 5 cases treated by me 3 were of a mild type associated with the warm weather. These were completely relieved whilst the treatment lasted, but relapsed when it was discontinued. The other two cases occurred in boys of 14, and were of a severe type. The condition had persisted for some months in spite of energetic measures taken to ensure cleanliness, and despite the continued application of drying and disinfectant powders. In both of these two latter cases there were blisters and abrasions, and in both cases the condition was completely cured in the course of three days by the application of glycerine well spread over the soles and toes before the socks were put on, this being repeated each morning as long as was necessary (three times in both cases).

The substances which give rise to the clinical symptoms of bromidrosis are to be regarded as products of protein disintegration, resultant on the action of bacterial enzymes. The actual substances present vary in nature and amount from time to time; among the most important are certain aromatic bodies, probably indol and perhaps skatol; these in conjunction with certain fatty acids give rise to the offensive smell, and no doubt help to aggravate the cutaneous lesions. Another and possibly the most harmful body is ammonia. This alkali, even in dilute solutions, has, as is well known, a relatively strong solvent and destructive action on keratin; and it seems probable that it is owing to its action on the skin that blisters and abrasions so readily occur in patients suffering from bromidrosis.

The addition of glycerine and various carbohydrates to the medium in which the indol-producing bacteria are growing prevents the formation of this substance. In addition, in place of an alkaline medium the fermentation of the glycerine leads to the production of a marked acidity. In treatment, then, the application of glycerine, while not inhibiting the growth of the bacteria, might be expected to prevent the formation of indol and other end products of protein destruction, and to substitute an acid for an alkaline medium in contact with the skin of the foot. This expectation was realised in my cases.

Bromidrosis as a clinical entity is probably not common in the army under normal circumstances, but even about 1 per cent. in a large army would make a considerable total of cases, which could probably be treated successfully by the method here advocated. It is, however, to a wider issue that I wish to direct attention. From time to time we hear of forced marches under conditions in which particular care of the feet, and probably even measures for securing ordinary cleanliness, are out of the question. Under these circumstances bacteria on the feet are likely to flourish, and the deleterious products of their activity to make themselves felt on the skin, with the result that blisters and abrasions readily form and have a very poor chance of healing; this, of course, especially during hot weather. It is suggested that the application of glycerine by preventing the formation of noxious products would enable the skin to be kept in a healthy condition, and for a time would do away with the necessity for washing. In practice the treatment presents no difficulty, involving as it does nothing more than the occasional application of glycerine in relatively very small quantity. I think that the use of glycerine should have advantages over the rather opposite measures often adopted, designed to dry and harden the skin of the feet. One effect of the glycerine, of course, is to make the skin moist; that does not, however, mean that the horny outer covering, which is the true protective layer, has been softened. On the contrary, whilst retaining its protective qualities, the skin is rendered supple, and it would seem fair to argue, as in the case of a material such as leather, that a supple and pliant fabric will wear better than a hard and brittle one. This last point, however, is a matter for experiment, and no doubt some other substance acting on the same principle could be substituted for glycerine if it seemed advisable.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY.

Introductory Address.—Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 20th, Dr. ALBERT GRAY (Glasgow), the President, being in the chair.

The PRESIDENT, in the course of a brief Introductory Address, gave a review of otology and its relationship to bacteriology and the wider subject of pathology. The problems already solved by otology were very great; 20 or 30 years ago but little could be done for a case of suppuration of the middle ear in staving off the ultimate fate of the patient; yet now these cases were successfully treated, either by operation or without. The number of lives saved and the amount of restoration, or at least of improvement, of hearing gave much hope for the future. But there were problems met with in the specialty which remained misty, and that more progress had not been made in their solution was probably due to the discoveries of Pasteur and Lister having so concentrated the attention of pathologists upon micro-organisms and their part in disease that too little attention had been given to the tissues themselves. Yet so widely different were the tissues of various people that even when the degree of invasion of organisms was equal in a number of patients the amount of response was not equal, nor could it be accurately forecast. Disease was the response of the animal to injury, and however plentiful the bacteria there could be no disease without the animal to manifest it. When a certain agency was at work in the human body the response was given a definite name, but it was never the same disease, exactly the same in behaviour. The individual was therefore by far the more important factor, the external factor the less important. Some disabilities were inherited, and no sort of outside influence could produce them; an instance of this was Daltonism or colour-blindness. A less noticeable case was that of arterio-sclerosis, with which could be classed otosclerosis. Some people, however outrageous their lives over a long series of years, enjoyed a green old age without suffering from arterio-sclerosis, while others had it in comparative youth. It seemed as if the initial defect was so strong in the fertilised ovum that it would come to light whatever the conditions of life. In many cases of otosclerosis the exciting agent was such a disease as typhoid fever, prolonged anæmia; even pregnancy might determine its onset. And though the Mendelian law was doubtless true of plant characters and of such inherited qualities as night-blindness, it did not apply to such a condition as arterio-sclerosis, nor, according to Mott's observations, to the neuroses. And probably the reason was that these latter depended largely on the process of repair being deflected from its normal function, such as by the influence of lead or other poison, and this complication by an outside influence naturally prevented it conforming to a law based upon pure heredity. Even in malignant disease there was a certain amount of inherited tendency, but an accident would largely determine the site and time of the manifestation. Knowledge was now fairly definite as to how repair of tissue took place, but he had never yet seen or heard the question propounded, "*Why* does tissue heal?" Why did not a wound granulate at the edges and remain open instead of closing? The answer to this question would mark a great advance and open the way to the solution of many problems.

Mr. W. M. MOLLISON showed the Brain of a patient who was exhibited at the section last year, he having died some weeks after the operation. The tumour, a glioma, was found in the position assigned to it during life—namely, about the left cerebello-pontine angle. There was an extensive hæmorrhage into the growth, and on one side was a cystic cavity which was opened at the operation.—Mr. C. E. WEST said it was a class of case difficult to diagnose, and presenting a very formidable problem in treatment. He thought the collection of fluid simulating a cyst was cerebro-spinal fluid. He did not think the exhaustion of the patient was due to the loss of cerebro-spinal fluid, for, provided patients were given plenty of fluid, they could stand the withdrawal of quite large quantities of cerebro-spinal fluid. And there was no evidence in the brain of infection of meninges, such as Mr. Mollison feared might have occurred.—Mr. G. J. JENKINS also discussed the case, and Mr. MOLLISON replied.

Dr. V. H. WYATT WINGRAVE exhibited a series of slides illustrating Lumbar Puncture Fluid in Aural Cases, and in his demonstration of them pointed out that in cases which were probably acute exacerbations of old and long-standing trouble the bacteria were nearly always polymicrobic, so varied as almost to present the characters of a throat film. In acute cases there were generally plenty of bacteria, but usually only of one or two varieties, the most interesting being the bacillus capsulatus mucosus. The cerebro-spinal fluid, especially in ear work, might be quite clear at the first or second withdrawal, but subsequent ones were either cloudy or full of flakes. In most cases of severe middle-ear infection the normal alkaline reaction of the fluid was much reduced, or it might even become acid. This had an important bearing on the treatment by urotropine.

Mr. WEST showed a male patient, aged 69, upon whom he had operated for Carcinoma of the Pinna. On admission to hospital he had a large ulcerated septic growth involving the inner aspect of the tragus, the external meatus, and the concha on the left side. The tissues on the posterior aspect of the pinna and over the mastoid region were œdematous and brawny, and one or two small glands could be felt in the upper part of the anterior triangle of the neck. The extensive operation included a radical mastoid, with wide exposure of dura mater above, and removal of neighbouring lymphatic territory. A graft was afterwards applied. The specimen was exhibited.—Mr. JENKINS and the PRESIDENT discussed the case, and Mr. WEST replied.

Dr. DUNDAS GRANT exhibited and demonstrated a Cold-air Labyrinth-testing Apparatus, which consists of a metal tube covered with an absorbent linen webbing and coiled in the form of a hollow cone. The absorbent covering is well wetted with chloride of ethyl, and air is projected through the tube by means of ordinary spray bellows. Inflation is continued until nystagmus is, or ought to be, induced—a period of some 30 seconds. The temperature of the air was about

44° F.—Mr. E. D. Davis thought the apparatus could be modified for the use of hot air also.—Mr. J. F. O'Malley thought the instrument possessed advantages over Barany's, because with the latter vaporised ether was employed, and it was not always desirable to introduce a drug.

SECTION OF DERMATOLOGY.

Exhibition of Cases.

A meeting of this section was held on Nov. 19th, Dr. J. J. Pringle, the President, being in the chair, when the following cases were exhibited.

Dr. P. S. Abraham: A case of Lupus Pernio on the hands and ears of a young Belgian with a family and personal history of tuberculosis.—The President regarded it as a typical example of the condition as first described by Sir Jonathan Hutchinson in this country and afterwards by Besnier and others on the Continent.—Dr. H. G. Adamson and Dr. J. H. Sequeira agreed with the diagnosis, the former suggesting X ray treatment and the latter static electricity for the relief of the chilblain circulation.

Dr. J. M. H. MacLeod: A case of an unusual Soft Nævus on the head of a young child.—Dr. A. Whitfield said he had no doubt that it was a soft mole, and remarked how readily a history of maternal impression could be obtained in these cases.—Dr. Sequeira had seen a similar case associated with the presence of a coloboma on the same side.—Dr. Adamson thought a section would show the growth to be a verrucose linear nævus.—Dr. E. G. Graham Little and Dr. Abraham also contributed to the discussion.

Dr. S. E. Dore: A case of Lichen Spinulosus in a child aged 8 years, following an attack of pneumonia.—The President said the condition did not appear to be fully known to French dermatologists, by whom it was apparently confused with spiny tuberculides. He agreed that there was no evidence of tuberculosis in the present case.—Dr. Adamson remarked that it was sometimes difficult to distinguish lichen scrofulosorum from lichen spinulosus, but he did not consider the case shown as tuberculous. He regarded it as related to lichen planus, and thought that lichen spinulosus in an adult meant that the patient had had, or would have, lichen planus.—Dr. Whitfield agreed with the exhibitor that external irritation might give rise to the over-production of horny tissue. Spines might be produced in connexion with seborrhœic eczema, lichen planus, syphilides, and in tuberculides.—Dr. Graham Little thought the microscopical appearances of the papules resembled those of pityriasis rubra pilaris rather than those of lichen planus.

Dr. W. K. Sibley: A case of Psoriasis associated with Extreme Onychogryphosis of the Toe-nails.—The President had never seen a similar case of the associated occurrence of the two diseases, but thought the toe-nail condition might be an exaggerated degree of the psoriasis, which affected the subungual fold of the finger-nails in the usual characteristic fashion.—Dr. G. Pernet had not seen the toe-nail condition in so young a patient nor its association with psoriasis.—Dr. Whitfield suggested that creasote internally might be tried as he had found it of great value in severe cases of psoriasis.—Dr. A. Eddowes, Mr. H. C. Samuel, and Mr. W. J. Midelton further discussed the case.

Dr. Sequeira: A case of Lichen Plano-Pilaris.—The President said the case was the most severe and extensive example of the disease he had seen, but it was absolutely characteristic.—Dr. Little, Dr. Adamson, Dr. Whitfield, Dr. Pernet, Dr. Eddowes, and the President discussed the relationship between the elementary lesions of lichen spinulosus, lichen planus, and pityriasis rubra pilaris.

Dr. Eddowes: A case of Rodent Ulcer of the Right Lower Eye-lid.—Dr. MacLeod advocated the use of radium as the best method of treatment of rodent ulcer in this position; he had used carbon-dioxide snow in a considerable number of cases, but had never had a permanently successful result from it.—Dr. Graham Little said he had observed a series of cases in which snow had proved successful.—Dr. Whitfield and Dr. Pernet agreed that CO_2 snow was unsatisfactory.—Dr. Sibley thought that snow should be followed up by X rays.—The President and Dr. Sequeira supported Dr. MacLeod's views.

Dr. Graham Little: 1. A case of Papulo-Necrotic Tuberculide. 2. A case of ? Dermatitis Repens which the President said he regarded as a typical one of lupus modified by treatment, and Dr. Adamson and Dr. Dore concurred in that view.

Dr. A. Winkelried Williams: A case of Leprosy treated with benefit by a vaccine prepared from the patient's own lesions.—Dr. Graham Little had seen improvement take place in a patient treated in a similar manner at St. Mary's Hospital.—Dr. Pernet and Dr. Sequeira also spoke.

SUBSECTION OF PROCTOLOGY.

Exhibition of Cases.—Injury to the Bowel from Shell and Bullet Wounds.

A meeting of this section was held on Nov. 11th, Mr. F. Swinford Edwards, the President, being in the chair.

Mr. Aslett Baldwin showed a woman, aged 76½, upon whom he had performed an Abdomino-perineal Excision of the Rectum.

Mr. Ivor Back described an obscure case of Œdema of the Sigmoid Mesocolon in which at operation the sigmoid lay in a groove in the intensely œdematous mesocolon. He invited suggestions as to the pathology of the condition.

Mr. W. Sampson Handley showed a case of apparently inoperable Carcinoma of the Rectum which became operable under radium treatment. The patient had remained free from recurrence up to the present, a period of about a year.

Mr. J. P. Lockhart Mummery read a paper on Injury to the Bowel from Shell and Bullet Wounds, in which he entered a strong plea for the expectant and conservative treatment of those injuries. He remarked that the most difficult cases were associated with fracture of the pelvis and sepsis, and described a case where a fæcal fistula opened by a traumatic aperture through the ilium. The hole in the bowel was closed by suture, and recovery was complete. For such cases he considered, in general, temporary transverse colostomy advisable.

A discussion followed, in which the President and others joined.

Æsculapian Society.—A meeting of this society was held on Nov. 20th, Dr. David Ross, a past President, being in the chair.—Dr. Leonard Williams conducted a clinical afternoon and showed: 1. A girl, aged 19 years, with Goitre, the right side being cystic. She also had exophthalmos and high arched palate. There was no heart trouble or other evidence of Graves's disease. Her eyebrows and hair generally were normal, but the mammary glands were infantile. The exophthalmos, it was pointed out, was due to adrenal insufficiency. Simple cystic goitre without hypertrophy. Treatment consisted of small doses of thyroid extract under observation. 2. Enlarged Thyroid of two years' standing in a woman, aged 29, who looked over 40 years of age, her hair being quite grey and her breasts flat, instead of being hard and round as in Graves's disease. The condition was due probably to toxæmia arising in the mouth or intestines. Short-circuiting had proved successful in two or three such cases.—Dr. P. Hamill showed: 1. A man, aged 43 years, with Double Cervical Ribs and Wasting of Forearm and Hand of recent onset. The condition was improving under electric treatment. 2. Skiagrams of this and other cases.—Dr. Leslie Durno mentioned a case of a woman, aged 45 years, who suffered from cough; phthisis was suspected. On examination it was found that the patient had a dark fluid discharge from the vagina. Swellings were found above the pubis on both sides, that on the left being hard and that on the right soft. Fibroid was diagnosed and an operation was performed. The soft swelling was found to be a cystic ovary and was removed. The point in the case was that the patient had no finger or toe nails for some time before, but they were entirely restored three weeks after removal of the ovaries.—Dr. Williams suggested that the removal of the ovaries stimulated the thyroid to increased activity.

Hunterian Society.—A demonstration of skin diseases was given at the London Hospital on Nov. 25th. Dr. J. H. Sequeira showed the following cases: 1. Herpes Zoster in an infant aged 6 months. 2. Lichen Planus, which had started as an acute erythema. 3. A Syphilitic Tongue in a girl who had a primary scar on the face acquired at the age of 10 months. 4. A case of very deep Gummatous Ulceration and Bone Necrosis of the Face, showing the excellent results of salvarsan, followed by plastic operations. 5. A case of Terminal Necrosis of the Phalanges. 6. Multiple Leiomyomata of one side of the face and the other side of the neck. These were congenital and yielded to electrolytic treatment. 7. Epidermolysis Bullosa. 8. A case of

Gummata in a young congenital syphilitic, which were being treated by salvarsan suppositories. 0·1 grm. salvarsan was given daily for three days, and the course repeated after a few days' interval. It was thought that absorption of the drug through the portal circulation might lead to its being especially activated in the liver. It was too early to say much, but the results so far were encouraging. 9. A case of Exfoliative Dermatitis following Psoriasis.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A meeting of this association was held in the rooms of the Medical Society of London on Nov. 24th, Dr. David G. Thomson, the President, being in the chair.—The following resolution, having been passed by the council, was submitted to the general meeting and approved unanimously:—

> The council of the Medico-Psychological Association of Great Britain and Ireland direct the attention of the association to the hardships of the staffs of the Royal Asylums of Scotland, which are not included under the benefits of the Asylum Officers' Superannuation Act, and recommend that letters be written to the managers of the Royal Asylums, the Scottish Board of Control, and Sir John Jardine on the subject.

The question of holding the regular meetings of the association during the continuance of the war was then discussed. The council recommended that they should be held, but that the projected visit to Birmingham in February next be abandoned for the present and the meeting held in London without any festivities. This was agreed to.—It was announced that Dr. C. E. Hetherington, superintendent of the asylum at Londonderry, had been seriously assaulted and wounded by a patient, but it was hoped that the wound was not dangerous. Sympathy with Dr. Hetherington was expressed.—The meeting agreed to send a letter of condolence to the relatives of Mr. Sydney Nelson Crowther, superintendent of Netherne Asylum, who had enlisted as a motor-cyclist scout and was killed in action recently. A similar course was pursued in the case of the late Dr. Harold B. Shaw, of the Isle of Wight Asylum, who died after a short illness.—The President asked whether any member could give any information regarding the fate of Belgian asylums during the devastation of which that country had lately been the victim, but no information was forthcoming.

Reviews and Notices of Books.

Report on the English Birth-rate. Part I.: England North of the Humber.

By ETHEL M. ELDERTON, Galton Fellow of the University of London. London: Dulau and Co. 1914. Pp. 246. Price 9*s*.

THIS elaborate report, involving a large statistical collection of facts, treats of the changes that have occurred in the birth-rate of the districts specified in the title during the period between the years 1851 and 1906. It claims to have established definitely (1) that an immense fall in the birth-rate took place between 1876 and 1906; and (2) that this fall was due, not to any physiological decrease in fertility, but to a widespread and nearly universal artificial restriction of the family.

In view of the great and rapid decline of the birth-rate which, although previously recognised, has now been so clearly demonstrated by the author of this report as having taken place in the districts named since about the year 1876, it seems clear that some factor other than purely physiological must be sought for in endeavouring to find an explanation. It is indeed an already wide-spread opinion that, especially among the classes ranging from above a low "poverty" line to a high level of wealth, the notable decrease in the birth-rate in late years is mainly the result of the use of "preventives" to conception. It is true, however, that this opinion, though very generally held, is but an opinion, and has never been set forth with any such degree of cogency or supported by such relevant observations as are now furnished in the report before us. Weighty and interesting evidence is there set forth of the wide sale of "preventives" in these later years; and very significant stress is laid on the synchronism of the initial fall of the birth-rate with the active propagandism for the limitation of families pursued by Mr. Bradlaugh and Mrs. Besant and the failure of the prosecution to convict them for publishing their well-known work entitled "The Fruits of Philosophy." It may be admitted, indeed, that artificial prevention of conception is probably a very important factor at the present time in limiting the size of families, and that it contributed largely towards producing the special fall of the birth-rate under consideration. But, for all this, demonstration of the claim made that artificial prevention is the sole cause to be reckoned with is still to seek.

The aim of this work appears to be to show that physiological decrease in fertility has nothing, while artificial restriction has everything, to do with the decrease of the birth-rate; and, further, that artificial restriction is practised on the whole by the more "fit" members of the population, or such as are assumed to be "naturally" the better stocks. Thus the argument running through the report apparently postulates that the cause of the decline in the birth-rate must be *either* natural *or* artificial, and seeks to establish the latter largely by means of an attempt to exclude the former. And here it may be remarked that we are not aware of any body of opinion on this subject, such as is described in the introduction to this report, which excludes from its purview the probable factor of artificial prevention, and regards the fall in the birth-rate as wholly a natural process.

This attempt to exclude the physiological factor altogether and to leave the artificial one in sole possession of the field cannot be deemed convincing. The author does not seem to recognise the probable direct influence on many women of sustained expenditure of energy or of bodily labour in decreasing their fecundity; or that many women, already the subjects of ailments which in themselves tend to prevent or diminish fecundity, use preventives in dread of future pregnancies or of any pregnancy at all. The possible physiological and medical questions thus involved are lightly dismissed with the statement that "there is absence of evidence that higher wages, the pursuit of pleasure, and an increased luxury have produced partial sterility." There is a very considerable amount of evidence on this subject, drawn from the study both of man and other animals, which has been altogether ignored. It seems to us that no attempt to exclude, by such statistical methods as are followed in this paper, all the factors possibly involved in the study of the causes of the decline of the birth-rate is likely to be successful.

Exception again must be taken to the indefinite and erroneous use of the words "fit" and "fitter" in this report, a use which occurs in many other works dealing with human reproduction and sociological matters generally. These words are not used in the legitimate sense—i.e., the biological or so-called "Darwinian sense"—and, to say the least, they are used arbitrarily and ambiguously. The epithet "fit" or "fitter" is apparently applied to certain persons or classes who are more or less socially worthy in the opinion of the author; and the argument is that it is the "worse" stocks which are left to breed freely, while the "better" stocks are reduced in number by artificial restrictions.

But when the chosen standard, such as that of being well-housed, &c., by which betterness or "fitness" is measured, seems somewhat failing, recourse is had to the still vaguer standard, based on collected opinions, of "good health and habits," which are assumed to be "hereditary" qualities. Now although it may well be true that the use of "preventives" exerts its greatest restrictive influence on the birth-rate among the more prosperous and thrifty classes, there is no reason to accept the view that the actually more fertile classes are "naturally" or racially the worse classes.

Although in most places of this work the word "fitter" seems to stand for persons situated in more or less good social conditions, and thus assumed to be physiologically sounder and racially or hereditarily better, in one place (see footnote, p. 232 of report) it is stated that "if healthy parenthood is to any degree hereditary its limitation will destroy the action of reproductive selection—i.e., the survival in larger numbers of the more *fertile* stocks." Here it seems to be the more fertile stocks which are indicated as the "fitter." But it is nowhere shown that the socially "better" have ever been more fertile than the classes who are alleged to be the "less fit," and to have now the preponderance in the numbers of their families.

Full of highly interesting information as this able report undoubtedly is, and clearly as it has shown the probably great importance of preventive measures as a factor in the reduction of the birth-rate, it fails, according to our judgment, in its claim to have eliminated, by the method of exclusion which it follows, the material part that is probably played in this reduction by various physiological and pathological influences.

Die Vitale Karminspeicherung: ein Beitrag zur Lehre von der Vitalen Färbung, mit besonderer Berücksichtigung der Zelldifferenzierungen im entzündeten Gewebe.

Von Dr. K. KIYONO, Kioto (Japan). Mit 5 lithographischen Tafeln. Mit einem Vorwort von L. ASCHOFF. Jena: Gustav Fischer. 1914. Pp. 258. Price 16 marks.

THE "vital staining" of cells is no new process. As early as 1878 R. Heidenhain used sulphindigotate of soda in the investigation of the structure of cells. Later Ehrlich employed methylene blue, and as a matter of fact "vital staining"—that is, staining "*intra-vitam*"—has considerably increased our knowledge of minute structure, more especially as regards the liver and kidney, while Goldmann[1] and others, by using trypan blue and trypan red, still further advanced our knowledge and demonstrated the value of the method both for normal and pathological processes.

The method employed by the author was to inject into any convenient vein of rabbit, fowl, or other animal a watery solution of carmine dissolved in lithium carbonate. The injection was repeated at varying intervals and storage of the carmine particles in the several tissues investigated at varying periods after the injections. Intraperitoneal and subcutaneous injections were also used. The tissues were fixed in alcohol or formol. First, the general effects and the degree of storage in the several organs of normal animals were studied, beginning with the kidney, which was recently investigated by Ribbert, Aschoff, Suzuki, and others. The method showed that the renal tubule is even more complex than was surmised. The liver became red, and on investigation the protoplasm of the liver cells and the star cells of Kupfer was found to be loaded with carmine granules, while the epithelium of the bile-ducts was completely uncoloured. The brain and cord remained "snow white," while the pia mater and choroid plexus became red. In the lymphatic apparatus there was a granular colouration of the reticular endothelium, and also of the "histiocytic" macrophages, which are derivatives of the former. The lymphocytes and germinal centres were not coloured. The granules did not pass into the fœtus though the placenta itself was red. Special attention was given to the presence or absence of carmine granules in connective tissue, both in the normal condition and in inflammation—the fibroblasts always contained the pigment. The omentum was specially studied, as were its lymphocytes, plasma cells, clasmatocytes, and fibroblasts. The endothelium itself covering it stored up very fine carmine granules. The cell forms in serous fluids were next investigated. The behaviour of cells towards carmine during regeneration of the spleen, liver, and lymphatic tissue was also investigated, as were tumours and tuberculosis.

The method proved itself a successful adjuvant for pathologico-histological diagnosis. The special results obtained with the kidney, liver, suprarenals, and other organs are described and figured. The results as regards the epithelium of the skin and mucous membranes were negative, and carmine did not appear in the bile. The endothelium of serous membranes is coloured, while the endothelium of blood-vessels is but slightly affected. The cells, even during proliferation and mitosis, do not lose their granules. In tumours produced experimentally in fowls and mice the sarcoma cells of the former and the interstitial cells of the latter show granular depositions, very like those of the fibroblasts from which they are derived. In the corresponding cells of carcinoma no carmine granules were found.

This is an admirable piece of work, which continues and enlarges a subject which has already been so successfully worked at under the direction of Professor L. Aschoff in Freiburg i.B.[2] The plates show a very high degree of excellence.

British Rainfall, 1913.

Compiled under the direction of H. R. MILL, Director of the British Rainfall Organisation, by R. C. MOSSMAN and C. SALTER. With maps and illustrations. London: Edward Stanford. 1914. Pp. 476. Price 10*s*.

THE fifty-third volume of this invaluable work contains the records received from 5370 stations, an increase of 98 over the previous year. The general plan and scope remain the same as in former years, and it would be difficult to suggest any improvement; the regional maps that are now supplied add much to its interest. The mean rainfall for England in 1913 was 31·08 inches, being 4 per cent. below the average of the 35 years, 1875–1909; in Wales it was 51·47 inches, or 9 per cent. above the average; in Scotland there fell 42·67 inches and in Ireland 43·06 inches, these amounts being respectively 4 per cent. below and 7 per cent. above the average. The regular recurrence of two relatively dry years following or followed by a wet year was interfered with in 1910, when one wet year succeeded another, but the cycle again recurred in 1912 with a wet year, and we learn that "with a slight deficiency in general rainfall the year 1913 again conforms to the rule, although it would be premature to assert that the periodicity has been re-established. The periodicity applies to England and Wales, but not to the British Isles, as is inadvertently stated on p. 209. The greatest rainfall in the kingdom occurred at Loan, Loch Quoich (Inverness-shire), where 183·25 inches were recorded. In England, 165·44 inches fell at The Stye, near Scafell Pikes, Cumberland; in Wales, 167 inches were recorded at Crib Goch, on Snowdon; and in Ireland, 103·60 inches at Gearahameen, in the Gap of Dunloe. The least rainfall occurred at Crowle, Lincolnshire, where only 16·67 inches were registered. A special article by Mr. Mossman deals with the phenomena of the dry summer of 1913. During the months of July and August barometric pressure was above the average over the whole kingdom, and, contrary to ordinary experience, was highest off the west of Ireland and lowest over the North Sea. Temperature was below the average everywhere except in the south-west of England, the extreme south of Ireland, and in the central and western Highlands and extreme north of Scotland. Sunshine was very deficient throughout nearly the whole of England and Wales and the east of Scotland. Rainfall was below the average everywhere, except in a small area in Sussex, and for the greater part of the kingdom was less than half the average amount. The memoir of the late Sir John Murray, editor of the 50 monumental volumes of the "Challenger" report, is appreciative and interesting; it is written by Dr. R. H. Mill, honorary director of the British Rainfall Association, the general editor of the publication. It is regrettable that the British Rainfall Organisation is not more adequately supported. The expenditure of £1469 was not met by the receipts, a deficiency of £56 having to be made up by the honorary director. Municipal corporations and sanitary authorities would be well advised to give material aid to its work, which is of great value in relation to many matters of public health administration. We are glad to learn that Dr. Mill has returned from his six months' visit to New Zealand in better health.

---

[1] THE LANCET, August 23rd, 1913, p. 595.

[2] In this connexion see review in THE LANCET, May 17th, 1913, p. 1392, of somewhat similar work by T. Suzuki, "Zur Morphologie der Nierensekretion unter Physiologischen und Pathologischen Bedingungen."

Lehrbuch der ärztlichen Sachverständigen-Tätigkeit für die Unfall-, Invaliden-, Hinterbliebenen-, und Angestellten-Versicherungs-Geszetzgebung.

Bearbeitet von Dr. L. BECKER, Geh. Medizinalrat und K. Kreisarzt a. D., Gerichtsarzt b. O. Gross-Berlin. Seventh edition. Berlin: R. Schoetz. 1914. Pp. 628. Price, paper, 15 marks; bound, 16.50 marks.

FOR unconscionable titles no books come up to German books; this work would run little chance of misinterpretation if summarily entitled "Medicine and State Insurance." It deals with the social insurance laws of Germany as they have developed, from their origin in the "Insurance against Sickness" Act, dated June 15th, 1883, down to the six books and 1805 paragraphs of the "Reichsversicherungsordnung" of 1911. Dr. Becker says that about 27 million persons were insured by the State against accident in 1912, and that payments amounting to over 170 million marks were made to 1,168,403 insured persons or their dependents during the year. The insurance of workmen gave rise to arbitration (legal proceedings) in 117,805 cases during 1912.

Dr. Becker's book is divided into two sections. The first deals mainly with the legal aspect of State insurance in Germany, and extends to 111 pages. The second part is devoted to the various diseases or accidents that may affect different parts of the human body, the ways in which they may be distinguished from apparently similar conditions, the extent to which current legal practice awards their victims compensation, the principles upon which such compensation is awarded. Thus it appears that workmen who receive injuries in the neighbourhood of the spleen or elsewhere, injuries to bones, or who lose much blood, and afterwards develop leukæmia (generally of the myeloid type), may be said to be suffering from "traumatic leukæmia" and may receive full compensation. It has been held in the German courts that a fatal secondary "traumatic meningitis" may occur 7 weeks, 15 months, or even 30 months after an injury to the head; chronic myocarditis has been attributed to falls without any direct injury of the heart. The last 70 pages are occupied by considerations on the laws dealing with the insurance and payment of invalids, employees, and the survivors of employees in a general way. The book ends with a good index.

The fact that Dr. Becker's compendium has reached its seventh edition is proof enough of its excellence; from the medical point of view it is full of interesting and important information on the many subjects with which it deals. It must be of great value to all medical referees and to medical experts who have to face lawyers, and should find a place in all medical libraries.

Outlines of Biology.

By ARTHUR THOMSON, LL.D. Sixth edition. London: Henry Frowde and Hodder and Stoughton. 1914. Pp. 855. Price 12*s*. 6*d*. net.

THAT this handbook should have reached a sixth edition is strong evidence of its merits, for the field which it covers has been of late years abundantly cultivated. Professor Thomson has had no lack of competitors in his most praiseworthy desire to lay before the commencing student a general view of the facts and inferences of zoology. One of the features which have secured to the author the pleasure, and we hope the profit, of having arrived at a sixth edition is undoubtedly the trustworthiness of his statements of fact. Because it is so absurdly easy to falter, even in quite well-known anatomical details, for the most experienced of teachers (as others besides the author will most readily admit), Professor Thomson is to be particularly congratulated on the firm hold which he has been here shown to possess of the main facts of zoology. We have in more than one group looked very carefully for error, not in the least to triumph over the author, but to assist him in the production of an especially superior seventh edition. This search has only revealed trifling misstatements which are obviously *lapsus calami*. Thus we may point out that Professor Thomson, though nearly exact in his statement that the Platyhelminths agree in possessing no anus, is to be confronted with Odhner's discovery of a distinct anus in the trematode genus Haplocladus. Again, the proper name of the anaconda is not "Boa" but Eunectes murina. Finally, it is not absolutely, though very nearly, correct to say that "all tapeworms are hermaphrodite," since the genus Diœcocestus, as its name implies, is bisexual.

Les Maladies du Cœur et de l'Aorte et leur Traitement.

By Dr. ARTHUR LECLERCQ. Paris: Octave Doin et Fils. 1914. Pp. 552. Price 7 francs.

IN this work, which forms one of a series on "Les Maladies de la Cinquantaine," the author offers a good résumé of the modern methods and views concerning the study of diseases of the vascular system. In his introductory chapters on the abnormal heart he describes the modern methods of investigation of organic and functional disturbances.

A new feature, however, is the classification of the diseases of the heart with which the author expects to replace the older and inadequate arrangement. He would divide the diseases of this system into three great syndromes—cardio-sclerosis, cardio-arteritis, cardio-atheroma, and again aortic sclerosis, aortitis, and aortic atheroma—which classification he bases upon the etiological factors together with the clinical features. Nevertheless, he gives a readable and accurate account of the diseases according to the old nomenclature, though it is a little difficult to find these in his table of contents based upon this new plan. Some of his treatment is likewise novel, and what he calls rational. He holds that all methods of treatment should be directed towards combating the retention of water or urea or salt, and in fighting against the renal inadequacy. But under treatment he details the various cures, hygienic and dietetic, that are in use.

We consider that this book will well repay study in virtue of the simplicity of its language and the novelty of some of the ideas.

LIBRARY TABLE.

The Intensive Treatment of Syphilis and Locomotor Ataxia by Aachen Methods. By REGINALD H. HAYES, M.R.C.S.Eng., &c. London: Baillière, Tindall, and Cox. 1914. Pp. 64. Price 3*s.* 6*d.* net.—Almost all advocates of salvarsan agree now that mercury is a most useful adjunct or even a necessary addition to the treatment by "606," and many with much experience in the treatment of syphilis declare that mercury surpasses its more recent competitor in trustworthiness. Of all the methods of administering mercury none is more effective than that associated with the name of Aix-la-Chapelle, and no better exposition of the method as practised there can be found than that contained in this little work. The method is fully described, and this book should be especially useful at a time when it is not possible, owing to the war, to send patients to Aachen.

Practical Bandaging, including Adhesive and Plaster-of-Paris Dressings. By ELDRIDGE L. ELIASON, M.D., Assistant Surgeon, University of Pennsylvania Hospital, &c. With 155 original drawings and photographs. London and Philadelphia: J. B. Lippincott Company. Pp. 124. Price 6*s.* net.—This is a lavishly illustrated manual, written for students and nurses in a simple and non-technical manner. Every conceivable bandage is separately and fully described, and (in nearly every case) illustrated. The subject is divided under the five heads of roller bandages, miscellaneous bandages, elastic bandages, adhesive dressings, and plaster-of-Paris bandages. The figures, many of them from photographs, are extremely clear. No one could desire a better handbook either for learning or for reference. The price may limit its circulation amongst students and nurses, at any rate in this country.

MISCELLANEOUS VOLUMES.

Mr. Joseph Jacobs, in a charming introduction to *Old French Romances, Done into English* by WILLIAM MORRIS (New edition. London: George Allen and Co., Limited. 1914. Pp. 180. Price 2*s.* 6*d.* net), tells us that the unquestioning, if somewhat external, piety, the immutability of the caste system, the spirit of adventure, the frankly physical love of woman, the large child-like wonder, are of the essence of romance. These qualities are certainly present in the four representative stories in this volume. The stories are the Tale of King Coustans and the Emperor, the Friendship of Amis and Amile, the Tale of King Florus and the Fair Jehane, and the History of Oversea. The quaintness of diction of the Romance tongue was reconstructed in English with remarkable fidelity by the late William Morris, and the stories glow with the mellow aura of their age and clime.——In MAXIM GORKY'S *Tales of Two Countries* (London: T. Werner Laurie, Limited. Pp. 243. Price 6*s.* net) the two countries are Italy and Russia, and the majority are infused with that sadness mingled with laughter which is characteristic of Russian art. Of the Italian tales the most striking are, to our mind, "The Simplon" and "The Traitor's Mother," while "A Message from the Sea" is a forcible picture of the Italian sea-coast and its scenery. Of the Russian tales perhaps the best is the cynical tale called "Hard to Please." Most of the stories are very slight in construction.——The author of "Elizabeth and Her German Garden" has depicted for us in *The Pastor's Wife* (London: Smith, Elder, and Co. 1914. Pp. 484. Price 6*s.* net) a book worth reading at the present juncture for the glimpse that it gives of certain phases of German village life. It is written in the clever author's best style. Particularly as the daughter of an English Bishop, the pastor's wife is an improbable person in real life, but she makes an admirable foil to the character of the German pastor who regards his wife as a physiological machine for the manufacture of babies and is concerned far more with plant fertilisers than with the duties of his cloth.

Several other novels are before us. A very clever, but mentally warped medical man, in MARY KERNAHAN'S novel, *Dr. Ivor's Wife* (London: George Allen and Co., Limited. 1914. Pp. 375. Price 6*s.* net), enters into a simply formal marriage with a poor schoolmistress in the country town in which he practises, to fulfil the terms of a will whereby the testatrix, an aunt of the doctor and a friend of the schoolmistress, leaves her money to him contingent upon this marriage taking place. In this novel a considerable acquaintance is shown with the *vie intime* of the practitioner of medicine. The story develops naturally, and we will not spoil the reader's pleasure by hinting at the upshot. The doctor is painted at the outset in what seem to us unnecessarily repellent colours, but his wife is a good portrait study.——*One Man's Way*, by EVELYN DICKINSON (London: George Allen and Co. 1914. Pp. 348. Price 6*s.* net), is the tale of an accomplished young medical man whose elemental passions, buried for a while in a Devonshire village, break loose under the demoralising influence of a half-French degenerate, the guest of his placid wife. Love as felt by the savage and by the higher products of human evolution is shown in contrast, and very decently shown. The medical colour suggests considerable acquaintance with facts.——*A Daughter of Debate*, by Mrs. AMBROSE HARDING (London: T. Werner Laurie, Limited. 1914. Pp. 343. Price 6*s.* net), deals with a social problem—that presented by the relations which should exist between white and negro races.——In the 16 little stories collected under the title of *Lovers' Meetings*, and written by KATHERINE TYNAN (London: T. Werner Laurie, Limited. 1914. Pp. 314. Price 6*s.* net), love is by no means restricted to the emotion of the sexes. Mother love and the affection engendered by early association with institutions also come under the term as used by the author, who shows an intimate knowledge of human character, and depicts it simply and sympathetically with humour and pathos.——*Queer Stories from Truth* (Twentieth Series. London: *Truth* Office. Pp. 252. Price 1*s.*) are now too well known to require more than the briefest mention. The present series, consisting of 28 stories, is up to the usual good standard.——The monosyllabic title *Strike*, which Mr. FREDERICK WATSON has given to "A Story in Dialogue" (London: Lynwood and Co. 1914. Pp. 166. Price 1*s.* net), is apparently intended to have a double meaning. The story, which uses a strike of workmen as a peg upon which to hang a diatribe on social unrest and the position of women, is not particularly entertaining, and stories, *quâ* stories, should certainly possess that attribute. As an argument it is not convincing.

JOURNALS AND MAGAZINES.

British Journal of Inebriety.—In the new quarterly number Mr. J. W. Astley Cooper discusses the Proposed Legislation for Inebriates, his contention being that, while changes in the law are urgently needed to bring the inebriate under control, those persons under whose care the patient has been placed should be thereafter empowered to exercise their authority with as few rules and regulations as possible. Mr. Cooper gives a qualified approval from this point of view to the amending Bill recently before Parliament, but considers that its provisions still show too much deference to prejudices in favour of the liberty of the subject.—Dr. T. Claye Shaw, in a brief paper on the Alcohol Problem of To-day, points to the gratifying increase of temperance in the masses of the population, and urges counsels of reasonableness and moderation on the over-zealous advocates of total abstinence, with whose principles, however, he expresses his personal agreement on scientific grounds.—An article by Mr. Theodore Neild on Chronic Alcoholism and Reproduction summarises (from a review by Dr. R. Wlassak) the results of the very important researches of Dr. Bertholet, of Lausanne, into the effect of chronic intoxication by alcohol on the reproductive glands. Bertholet's inquiry dealt with the pathological conditions found in a series of 163 "drinkers" (i.e., persons habitually consuming more than 100 c.c. of pure alcohol) and in a series of 100 "non-drinkers." The most important fact established by the inquiry is that testicular degeneration is by far the most frequent morbid condition which the bodies of inebriates show. It was present in 86 per cent. of the "drinkers," as against 29 per cent. of the "non-drinkers." This result is the more noteworthy as the individuals in the alcoholic class were of lower average age, only 12 per cent. being over 60, while the corresponding ratio in the non-drinking group amounted to 28 per cent. Bertholet classified his cases on the basis of a minute histological examination, the result being to bring out more clearly the relation of degenerative change to alcoholic poisoning. Thus the most extreme stage of morbid alteration characterised by complete shrinkage of the cellular elements and entire absence of spermatozoa was met with in 55 per cent. of the alcoholic cases, but only in 15 per cent. of the subjects regarded as "non-drinkers." Mr. Neild's paper should be useful in directing attention to Bertholet's original memoir ("Action de l'Alcoolisme Chronique sur les Organes de l'Homme, et sur les Glandes Réproductrices en Particulier." Lausanne, 1913).

The British Dental Journal.—In a paper read before the Royal Society in March Mr. J. Howard Mummery recorded his observations on the nature of the tubes in marsupial enamel and its bearing upon enamel development. An abstract of the paper, with a reproduction of the illustrations, appears in the Nov. 15th issue of this journal. The author considers that the tubes run between the prisms and not in the prisms. In marsupial enamel the cement substance is imperfectly calcified compared to that in higher mammalian enamel, and this imperfect calcification allows the penetration of the dentinal fibril from the previously formed dentine. The fibril has a distinct tube wall and is resistant to the action of acids.—In the same issue Dr. H. R. Burpitt contributes a short paper on the relationship between defective teeth and malnutrition in children. 800 children were examined and divided into two classes as to whether more or less than four teeth were carious. He finds the boys and girls with the worst teeth are quite well nourished as the average of the children. The work would have been of more value if the condition of children with functional mouths had been recorded against those with advanced caries.—There is also an interesting article on the Naval Dental Service by Mr. E. E. Fletcher.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WE continue our report of the proceedings of the General Medical Council for

TUESDAY, NOV. 24TH.

A Removal from the Register.

A report was received from the Executive Committee stating that it had considered a request, transmitted by the Scottish Branch Registrar, from Robert Ramsey, registered as of 2, Sandyford-place, Glasgow, W., M.B., Ch.B. 1901, U. Glasg., F.R.C.S. Edin. 1904, F.F.P.S. Glasg. 1905, for the removal of his name from the Medical Register on the ground of his having ceased to practise. A statutory declaration in accordance with the Standing Orders had been supplied, and the bodies concerned stated that they had no objection to the removal of the name from the Register. The committee resolved "that this request be reported to the Council, with a recommendation that it be acceded to."

The PRESIDENT moved that the recommendation of the report should be adopted by the Council.

The motion was agreed to.

Inspection and Visitation of Examinations.

The following report was received from the Executive Committee :—

At its meeting on July 13th, 1914, the Executive Committee considered business arising out of the following resolution adopted by the General Council on June 1st, 1914 :—

"That it be delegated to the Executive Committee to make all necessary arrangements for the inspection and visitation of qualifying examinations directed to begin in 1915, and to nominate to the Council at its November session suitable persons for appointment as inspectors."

According to the Standing Orders, three inspectors—one for medicine, one for surgery, and one for midwifery—must be appointed for definite periods. The remuneration is fixed at five guineas for each day during which the inspector is absent from home on the business of the Council, together with an allowance for his actual travelling and hotel expenses. The committee authorised the Registrar to obtain from the licensing bodies the dates of their qualifying examinations to be held during the year 1915 and to take other preliminary steps.

The committee on the same day also considered business arising out of the following resolution adopted by the General Council on June 1st, 1914 :—

"That it is advisable that all examinations conducted for the purpose of conferring the several registrable degrees, diplomas, or certificates in Sanitary Science, Public Health, or State Medicine, specified in Table G at page lxxv. of the Medical Register, should be inspected, and that it be remitted to the Executive Committee to consider and report upon the necessary arrangements for the inspection."

The committee resolved to recommend :—

(*a*) That an inspection of all the examinations for Diplomas in Public Health should be commenced in 1915. Those bodies whose examinations in Public Health have been instituted since the last inspection should be first inspected.

(*b*) That one inspector should be appointed for all the examinations, and should be remunerated on the same scale as the inspectors of the final examinations. Where practicable a member of the Council should accompany the inspector as visitor. The further consideration of the appointment of an inspector was postponed till the next meeting of the committee.

At a later meeting held on Sept. 15th, 1914, subsequent to the outbreak of the war, the committee considered what further action, if any, should be taken in regard to the visitation and inspection of qualifying examinations, and of examinations for diplomas in public health, respectively, during the year 1915, whereupon it was resolved: "That the resolutions of July 13th, 1914, be rescinded, and that the Executive Committee report to the Council that in view of the present unusual conditions it is inexpedient to proceed with the proposed inspection and visitation of qualifying examinptions and of examinations for Diplomas in Public Health during the year 1915."

On the motion of the PRESIDENT it was agreed to adopt the recommendations of the committee's report and to postpone the visitation and inspection for the present.

WEDNESDAY, NOV. 25TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair.

Charges against Practitioners.

The Council considered charges brought against practitioners.

The first case to be considered was that adjourned from May 29th, 1914, of William Blaikie Mason, registered as of 218, Somers-road, Southsea, M.R.C.S. Eng. 1893, L.R.C.P.

Lond. 1893, who had been summoned to appear before the Council on the following charge :—

That being a registered medical practitioner you on Nov. 1st, 1913, signed a certificate that one, Patrick Matthews, of 46, Raglan-street, Southsea, was suffering from gastric colic and was unable to follow his occupation, whereas you had neither seen nor examined the said Patrick Matthews, which said certificate was untrue, misleading, or improper. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants were the Lords Commissioners of the Admiralty. At the conclusion of the proceedings in May the President announced the decision of the Council as follows :—

Mr. William Blaikie Mason, I have to inform you that the Council has found that the facts alleged against you in the notice of inquiry have been proved ; that the Council takes a very serious view indeed of the offence you have committed ; and that it has already marked its sense of the gravity of such offences by issuing in the medical journals and elsewhere in November, 1911, a warning notice as follows :—

Whereas registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates signed by them in their professional capacity for subsequent use, either in courts of justice or for administrative purposes. And whereas such certificates include, *amongst others :*—

Certificates :—

(*a*) Under any statute relating to births, deaths, or disposal of the dead.
(*b*) Under the Lunacy Acts.
(*c*) Under the Vaccination Acts.
(*d*) Under the Factory Acts.
(*e*) In relation to children or to excusing school attendance.
(*f*) In connexion with sick benefit, insurance, and friendly societies.
(*g*) In connexion with workmen's compensation.
(*h*) In connexion with naval or merchant shipping.
(*i*) For procuring the issue of Foreign Office passports.
(*j*) For excusing attendance in courts of justice, in the public services, in public offices, or at ordinary employments.

And whereas it has been made to appear to the General Council from time to time that some registered medical practitioners have given and signed untrue, misleading, or improper certificates of the above specified or other descriptions.

Now, therefore, the General Medical Council hereby give notice that any registered medical practitioner who shall be shown to have given any untrue, misleading, or improper certificate, whether relating to the several matters above specified or otherwise, is liable to be adjudged by them to be guilty of "infamous conduct in a professional respect" and to have his name erased from the Medical Register under Section 29 of the Medical Act, 1858.

In order to give you an opportunity to prove to the Council that you realise the gravity of your offence, and to produce evidence from your professional brethren regarding your character and conduct generally, the Council has postponed judgment till the November session, when you will be required to attend to produce testimony to the effect above specified.

Mr. MASON attended in person, but the complainants, the Lords Commissioners of the Admiralty, wrote to say that they did not intend to be represented.

Mr. MASON submitted to the Council numerously signed testimonials as to his professional character from medical men in Portsmouth and its vicinity and also from prominent citizens.

The PRESIDENT announced the decision of the Council as follows : Mr. William Blaikie Mason, I have to inform you that the Council does not see fit to direct the Acting Registrar to erase from the Medical Register the name of William Blaikie Mason.

The Council proceeded to the consideration (adjourned from May 28th, 1914) of the case of Alexander Girvan, registered as of 8, Palace-street, Buckingham Gate, London, S.W., M.B., C.M. 1894, M.D. 1904, U. Glasg., who had been summoned to appear before the Council on the following charge :—

That being a registered medical practitioner you were on Dec. 4th, 1913 (after having elected to be dealt with summarily), convicted at the Westminster police-court of unlawfully and wilfully making a certain false declaration under and for the purposes of a certain Act relating to the registration of deaths and fined £10 and £10 costs.

At the conclusion of the proceedings on May 28th, 1914, the decision of the Council was announced by the PRESIDENT as follows : Mr. Alexander Girvan, I have to inform you that the Council has found your conviction for the misdemeanour alleged against you in the notice to have been proved ; that the Council takes the gravest view of the offence of which you have been convicted ; but that, having regard to the punishment which you have already received, the Council has suspended its judgment until the November session, when you will be required to attend and to produce evidence from medical men and others that in the interval your professional conduct has been without reproach.

Dr. Girvan attended, and was also represented by Mr. H. W. Wickham, counsel instructed by Messrs. Walton and Hurd, solicitors.

Mr. WICKHAM handed in testimonials from members of the medical profession to the effect that Dr. Girvan had in the interval conducted himself in consonance with the best traditions of the profession.

The PRESIDENT intimated the decision of the Council as follows : Mr. Girvan, I have to inform you that the Council has considered once more the conviction which has been proved against you, that the Council takes a very grave view of the misdemeanour of which you have been convicted, but in view of the certificates of character which have been put in on your behalf, the Council has not seen fit to direct the Acting Registrar to erase your name from the Medical Register.

The next case considered was that (adjourned from May 28th, 1914) of Haripado Chatterjee, registered as of 1, East View, South Moor, Stanley, Co. Durham, L.R.C.P & S. Edin., and L.R.F.P.S. Glasg. 1910, who had been summoned to appear before the Council on the following charge :—

That, being a registered medical practitioner, you, in the year 1913, accepted the post of medical officer of an association known as the South Moor Medical Association in the knowledge that such association had through its officials, by widely distributed circulars, by personal canvassing, and by solicitation of members of the Miners' Union in the South Moor district, sought to secure members of such association who, on joining it, would become the patients of the medical officer thereof.

And further that you have by public speaking in the South Moor district and by advertising in such speeches your own qualifications taken a prominent part in inducing and endeavouring to induce persons to join the said association and so to become your patients.

And further that throughout the year 1913, knowing that you were being advertised in the South Moor district as the doctor of the said association, you acquiesced in such advertising and continued to be employed as its medical officer.

And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants were the British Medical Association.

At the conclusion of the proceedings on May 28th, 1914, the decision of the Council was announced by the PRESIDENT as follows : Mr. Chatterjee, I have to inform you that the Council has carefully considered the facts alleged against you in the notice of inquiry, and has found that the following fact has been proved—viz., that you have by public speaking in the South Moor district and by advertising in such speeches your own qualifications taken a prominent part in inducing and endeavouring to induce persons to join the said association and so to become your patients, but that the Council has suspended judgment till the November session, when you will be required to be present and to produce evidence as to your professional conduct in the interval, and as to the methods of the association under which you have accepted employment.

The President explained to Mr. Chatterjee's solicitor, Mr. Stewart, that the other facts alleged in the notice of inquiry had not been proved to the satisfaction of the Council.

Mr. Chatterjee attended. Mr. W. E. Hempson, solicitor, represented the British Medical Association.

Mr. CHATTERJEE, addressing the Council, said that he had terminated his engagement with the South Moor Medical Association at the earliest possible moment. He had endeavoured in every way to act in strict accordance with the traditions of the medical profession and in harmony with the other medical practitioners in the district in which his practice was placed. He handed in testimonials as to his professional conduct in the interval.

The PRESIDENT announced the decision of the Council as follows : Mr. Chatterjee, the Council have carefully considered the evidence which you have brought on your own behalf and from two registered practitioners, and being satisfied that, as you severed your connexion with the South Moor Medical Association immediately, you could not bring the other evidence which you were required to furnish as to the methods by which this association is now conducted, the Council has not seen fit to direct the Acting Registrar to erase your name from the Medical Register.

The Council proceeded to the consideration (adjourned from June 1st, 1914) of the case of Caspar Denis Downing, registered as of 47, Mount Pleasant-square, Ranelagh, Dublin, L.A.H. Dubl., 1912, who had been summoned to appear before the Council on the following charge :—

> That, being a registered medical practitioner, you were convicted: "(1) On Feb. 22nd, 1913, at the City Police Court, Liverpool, of being guilty while drunk of disorderly behaviour in Windsor-street, Liverpool; (2) on August 2nd, 1913, at the City Police Court, Liverpool, of being guilty while drunk of disorderly behaviour in Boundary-street, Liverpool; and (3) on Dec. 13th, 1913, at the Inns Quay Police Court, Dublin, of being found drunk in a highway."

At the conclusion of the proceedings the President announced the decision of the Council as follows: I have to state that the Council has found that the convictions for misdemeanour alleged against Mr. Caspar Denis Downing in the notice of inquiry have been proved, but that judgment has been postponed until the next session of the Council in November, when Mr. Downing will be required to be present and to produce satisfactory evidence as to his conduct in the interval.

Mr. Downing did not attend nor was he represented.

Mr. Harper, the solicitor to the Council, stated that he had received from Mr. Downing on the previous day a telegram stating that he would be unable to be present.

The President announced the decision of the Council as follows: I have to announce that Caspar Denis Downing having been proved to have been convicted of the misdemeanour alleged against him in the notice the Council has directed the Acting Registrar to erase from the Medical Register the name of Caspar Denis Downing.

The Council then considered the case against Mr. Valleck Cartwright Mallan. This case was adjourned from May 28th, 1914. On that occasion the Dental Committee found that the following facts were established by the evidence :—

> The said Valleck Cartwright Mallan was registered in the Dentists Register on Dec. 6th, 1878, as "In practice on July 22nd, 1878," and his address in the Register for the current year is 106, Edgware-road, London, W.
>
> The said Valleck Cartwright Mallan practises at 106, Edgware-road aforesaid, and issues and distributes as widely as he can a card and an explanatory pamphlet advertising his practice. The card contains a number of illustrations of American plateless teeth; the pamphlet enlarges upon the advantages of consulting the said V. C. Mallan, and contains a photographic reproduction of a newspaper paragraph on the long-standing reputation of the said V. C. Mallan and his family since the beginning of the nineteenth century. The said V. C. Mallan stated that the paragraph appeared in the *Catholic Times*, and was not an advertisement, although he advertises in that paper.
>
> The complainants also submitted a two-column article which had appeared in the *Hampstead Advertiser* of July 17th, 1913, containing a portrait of the said V. C. Mallan, and photograph of a challenge cup which he had presented in connexion with local cricket. The said article contained a lengthy and puffing description of the said V. C. Mallam as a dentist as well as a public man interested in the public affairs of Marylebone.
>
> The complainants did not offer any proof that the said V. C. Mallan was responsible for this article, but he admitted in answer to questions that he had been interviewed by the *Hampstead Advertiser* and had given the information, some of which was untrue, therein contained; that, although he had not paid for it, he had subscribed for one hundred copies, which he had sent out to various people; and that he had, in fact, used the article as an advertisement for his practice.
>
> At the conclusion of the inquiry before the Dental Committee the said V. C. Mallan offered to give an undertaking that in future he would not advertise in any form of which the Council disapproved.

At the conclusion of the proceedings of the General Council on May 28th, 1914, the President announced its decision as follows: Mr. Mallan, the Council has considered the report of the Dental Committee in regard to the facts proved against you, and it has considered the undertaking which you have given, that in future you will not advertise in any form of which the Council disapproves. The Council has deferred the further consideration of your case to the November session, when you will be required to be present and to produce satisfactory evidence as to your conduct in the interval, with particular reference to the manner in which you have carried out the undertaking regarding advertising which you have given to the Council.

A further report on the case of Mr. Valleck Cartwright Mallan was now presented by the Dental Committee. It stated that at its meeting—

> Mr. William Fletcher Thomas Brown, managing clerk to Messrs. Bowman and Curtis-Hayward, gave evidence of a visit he had paid to the premises of the accused at 106, Edgware-road, W., and that the only difference he had observed in the appearance of the place since the hearing in May last was that the photographs of patients and testimonials from them had been removed from the entrance lobby. Mr. Turner stated that the complainants believed that the distribution of cards and pamphlets had ceased.
>
> The said Valleck Cartwright Mallan gave evidence on his own behalf and addressed the committee. He admitted the accuracy of Mr. Brown's evidence, but denied that he had broken the undertaking not to advertise which he had given to the Council, and contended that such undertaking was intended to apply only to the first ground of complaint (as to cards and pamphlets), and that he had implicitly kept his promise. The second ground related to a single past incident. As regards the third ground of complaint, he had not intended that to be included in his undertaking at all, and had removed the photographs and testimonials from the passage because the complainants had made such a point of them. But he had not altered his window, or the front of his premises, and, in answer to a question by the Chairman, the said Valleck Cartwright Mallan said that he refused to alter it, it meant his living, and rather than do away with his window or signs on his premises he would prefer to be off the Register.

Mr. Mallan attended, and the complainants, the British Dental Association, were represented by Mr. J. R. B. Hart, counsel, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

Mr. Mallan, addressing the Council, said that he had carried out his promise to the Council. There was nothing in the Dentists Act which prohibited a practitioner showing the mechanical part of his profession, and the Council's resolution of May 20th, 1894, did not apply either to the exterior or interior of any building. He maintained that advertising applied to circulars of a certain character which contained claims of superiority over other practitioners.

Mr. Hart submitted that the undertaking which Mr. Mallan had given had not been fulfilled.

The President announced the decision of the Council as follows: Mr. Mallan, I have to call your particular attention to what I am going to say to you now. The charge made against you included the following statement: "That being a registered dentist you have extensively advertised your practice ...... (*e*) by means of various conspicuous notices on the outside and inside of your premises at 106, Edgware-road, W., where you carry on your profession, of a shop window on the ground floor thereof filled with shelves of false teeth, and notices advertising your practice." The Council are not entirely satisfied that you fully understood the undertaking which you gave to them to be an undertaking to discontinue advertising by the particular means set forth in this paragraph of the charge. The Council recognise that you have carried out an undertaking to discontinue advertising by the other means specified in the charge. The Council desire me to impress upon you that the means of advertising specified in paragraph (*e*) of the charge are no less objectionable than the others, and fall within the resolution of May, 1894, of which you are aware. They propose to give you a further opportunity of discontinuing the objectionable forms of advertising which you have continued to adopt, and for this purpose postpone their judgment in your case until May next. A copy of this judgment will be sent to you in due course.

The Council then considered two complaints against practitioners together. The first was the case of James Shirran Abernethy Walker, registered as of 416, Oldham-road, Manchester, M.B., C.M. 1887, M.D. 1898, Univ. Aberd., who had been summoned to appear before the Council on the following charge :—

> That being a registered medical practitioner you gave under the National Insurance Acts 1911 to 1913 four certificates dated July 19th and August 7th, 18th, and 25th, 1913, respectively, certifying that you had on those days respectively seen one Henrietta Horridge, and that she was suffering from chest affection, and was thereby still totally incapable of work, whereas you had not on any of those days either seen or examined the said Henrietta Horridge. And that you authorised John Watt, a registered medical practitioner, to furnish similar certificates on your behalf in respect of the said Henrietta Horridge which were dated respectively July 28th and August 5th, 1913, whereas neither you nor the said John Watt had either examined or seen her on either of those days. All of which certificates were untrue, misleading, or improper. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The second was the case of John Watt, registered as of 416, Oldham-road, Newton Heath, Manchester, M.B., C.M. 1892, Univ. Glasg., who had been summoned to appear before the Council on the following charge :—

> That being a registered medical practitioner you gave under the National Insurance Acts 1911 to 1913 two certificates dated July 28th and August 5th, 1913, respectively, certifying that you had on those days respectively seen one Henrietta Horridge, and that she was suffering from chest affection and was thereby still totally incapable of work; whereas you had not on either of those days seen or examined the said Henrietta Horridge, both of which certificates were untrue, misleading, or improper. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The Council's attention was called to this case by the Manchester Insurance Committee.

It was agreed to take both cases together.

Dr. Walker and Dr. Watt attended in person, and were also represented by Mr. A. J. F. Wedderburn, S.S.C.

The complainants, the Manchester Insurance Committee, were represented by Mr. R. V. Clayton and Dr. T. A. Goodfellow, of the Medical Service Subcommittee, and Mr. J. E. Lilley, the clerk to the committee.

Mr. R. V. CLAYTON addressed the Council on behalf of the complainants. He said that the Manchester Insurance Committee had brought this matter forward from their Medical Service Subcommittee. They thought that the facts required some attention from the Council, although they did not wish to press in any way the case in such a manner as would lead to the deletion of the names of the practitioners from the Medical Register. Dr. Walker, as the panel doctor, attended Miss Horridge for some considerable time, and there was no doubt that Dr. Walker was the regular medical attendant of her and her family. On July 10th, 1913, sanatorium treatment was accorded to her and she entered a sanatorium, where she was until Oct. 23rd. That covered the period mentioned in the charge. He understood that Dr. Walker would not allege that he went to see her at the sanatorium. Under the provisions of the National Insurance Act, in the case of an insured person who was the inmate of a sanatorium, the law was that the moneys that would have been paid to the insured person, if that person had dependants, would not be paid if he had no dependents, but they would go to the committee of the district. The moneys making up the allowance of this woman should not have been paid to her but to the Manchester Insurance Committee. These facts having come to the knowledge of the Medical Service Subcommittee, they thought it desirable that the case should be brought to the attention of the General Medical Council in order that some admonition should be pronounced to Dr. Walker not only in his own interests but in the interests of other medical men in Manchester, and of the profession generally. The Manchester Insurance Committee had no desire to press the matter to any extreme because at the time that these events occurred the regulations with regard to the giving of certificates by medical men were not as well known, nor in as defined a form as they had since become. It was now one of the regulations of the Insurance Commissioners that the doctor giving the certificate must give it only on the day he actually saw the patient.

The certificates in question were handed to the Council, and this closed the case for the complainants.

Dr. WALKER then gave evidence on his own behalf, and stated that he had been 22 years in practice at Manchester. Dr. Watt had been his assistant for the last seven or eight years. During the whole of his professional career no complaint had ever been made against his professional conduct. His practice was one of the largest in Manchester. The Horridge family had been patients of his for 14 years, and he knew them well as most respectable people. He had acted as medical man for many friendly societies before the National Insurance Act came into operation, and he had to give certificates of incapacity upon forms provided by the societies. These were not initial certificates but continuing certificates, and merely certified that the person was still incapable of work. That continuing certificate was given without any reference to the date of examination, and the continuing certificate was always brought to him by the patient, who got it from the society. He did not keep any of them in stock.

Mr. WEDDERBURN: What had you come to regard as the essential of these continuing certificates?

Dr. WALKER: The essential part was that the person was incapable of doing work. Miss Horridge was seen by him in April, 1913, and he then granted her the initial certificate on the form required by the National Insurance Commission. He saw her regularly until she went into a sanatorium, and accordingly each week he granted a continuing certificate of incapacity. She never did continue to follow her occupation. When he granted the certificate of July 19th he knew that she had been sent to the sanatorium.

Mr. WEDDERBURN: Have you any distinct recollection of how you came to grant it?

Dr. WALKER: Yes. Mrs. Horridge, the mother, brought me a certificate. I said to her that I did not think I could sign it, but Mrs. Horridge replied that the insurance agent told her to bring it to me and it would be all right. The only thing that was in my mind was whether the person was incapable of work.

Did you appreciate the words on the form of the certificate that you were expected to see the patient on that date?—Those words were not in my mind.

You had sufficient knowledge of Mrs. Horridge to know that she was not a person to tell you wrongly?—I had sufficient confidence in what she told me as to the agent's statement.

You were perfectly satisfied that Miss Horridge was unfit?—I had no doubt.

Had you any knowledge that a member of the society getting sanatorium treatment was not entitled to demand sickness benefit?—I did not know anything about the law.

The PRESIDENT: You knew this certificate was for the purpose of getting sickness benefit.

Dr. WALKER: I must have known that.

Mr. WEDDERBURN: You were not aware that the girl was not entitled to get the money?

Dr. WALKER: No.

Now you recognise your mistake in not attending to the form of the certificate?—Certainly. The only fact that struck my mind was that she was incapable of work. He went on to say that he felt this charge very keenly and was very sorry for having made this mistake, and since the incident had occurred he had attended very carefully to the form in which certificates were given.

Dr. MCVAIL asked Mr. Clayton whether the Manchester Insurance Committee had considered removing Dr. Walker's name from the panel lists.

Mr. CLAYTON: No. We thought that that would be much too drastic.

Dr. WATT was then called as a witness. He had heard the evidence of Dr. Walker and concurred in his explanation as to the nature of the work and the different certificates that had been in use. He recognised that he should be very careful in regard to any other certificates, and on no account would he grant any certificate without seeing the patient on the day it was granted. He very much regretted having made this mistake.

Mrs. HORRIDGE gave evidence that she brought the certificates to Dr. Walker to his surgery for signature.

Mr. J. U. SMITH, a member of the Medical Service Subcommittee of the Manchester Insurance Committee, was called as a witness. He said that he found that Dr. Walker was one of the hardest working doctors in Manchester, and he attended with the greatest attention to his panel patients.

The further hearing of the case was adjourned and the Council rose.

THURSDAY, NOV. 26TH.

The Council resumed its sitting at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair.

Complaint against Practitioners.

The Council resumed the hearing of the case against Dr. Walker and Dr. Watt adjourned from the previous day.

Mr. WEDDERBURN addressed the Council on behalf of these two practitioners. He pointed out the great confusion which arose after the passing of the National Insurance Act as to the giving of certificates. Confusion was particularly pronounced with regard to the continuing certificates, and in the case of the Approved Societies these had continued to be in the same terms as the certificates which Dr. Walker and Dr. Watt had been in the habit of granting before the Act came into operation. What had fixed its mark in the mind of these two practitioners was that they should certify merely that there was incapacity at the date of the certificate. They had not realised the alteration that had taken place. They now admitted that they had committed an irregularity in this case, but it was not a gross one. The instructions issued by the National Insurance Commissioners showed that there had been a great deal of misapprehension in the minds of practitioners on this matter, and the circulars which had been issued showed that even in September, 1913, a very great deal of confusion still existed.

The PRESIDENT announced the decision of the Council as follows: Dr. Walker and Dr. Watt, I have to inform you that the Council have carefully considered the matters brought to their notice during this inquiry, and have decided that the facts alleged against you in the notice of inquiry have been proved to the satisfaction of the Council. The Council take a very grave view of any laxity on the part of medical men in regard to the giving of certificates, but we have taken account of the explanation of your conduct in this matter, and that you have offered assurances with regard to the more careful exercise of this responsibility in the future. We have taken these explanations and assurances as given in good faith, and have accordingly not seen fit to direct the Registrar to erase your names from the Medical Register.

Erasure from the Dentists Register.

The Council then took up consideration of the case of Cartwright Davis, registered as of 81, Knightsbridge, S.W., "in practice on July 22nd, 1878," in regard to whom the Dental Committee had found the following facts:—

The Dentists Register contains the following entry:—

Name.	Address.	Date of registration.	Description and date of qualification.
Cartwright Davis.	81, Knightsbridge, London, S.W.	1878, Dec. 31st.	In practice on July 22nd, 1878.

Information having reached the British Dental Association early in the present year that the person practising as above was neither Cartwright Davis nor a dentist, the Association, with the assistance of the officials of the Council, made careful and thorough inquiry and ascertained the following facts.

Cartwright Davis was a name under which a Mr. Mallan practised dentistry, and in 1878 registered under the Dentists Act. Some years ago he took as an assistant one John Edwin Sutton, who, however, never qualified as a dentist or registered. On the death of Mallan his widow carried on the practice through Sutton, who married her daughter, and since 1903 Sutton had regularly signed the returns to the Registrar of the Council in the name of Cartwright Davis, thereby maintaining that name upon the Register and himself practising as a dentist under that name.

The British Dental Association prosecuted Sutton under the Perjury Act, 1911, and pressed for his committal for trial at the Central Criminal Court. He was tried on July 21st, 1914, at the Central Criminal Court before the Common Serjeant, and pleaded guilty to the charge of unlawfully procuring himself to be registered in the name of Cartwright Davis on the Register of persons qualified to practise as dentists. The Common Serjeant bound Sutton over in a recognisance of £20 to come up for judgment if called upon, but seeing that this was the first case brought forward under the new Act he did not impose any other penalty.

The facts as above stated have been formally brought to the attention of the Council by the British Dental Association, and the committee is advised that as Sutton, by pleading guilty, admitted the facts, it is not necessary, in dealing with the question of the removal of the name of Cartwright Davis from the Dentists Register, to hold a formal inquiry and require further proof of the facts. The committee therefore, being satisfied that the facts are as above stated, report them to the Council.

By section 13 of the Dentists Act the Council shall cause to be erased from the Dentists Register any entry which has been inaccurately or fraudulently made.

After consideration *in camerâ*,

The PRESIDENT said: I have to announce that the Council, having considered the report from the Dental Committee, have directed the Acting Registrar to erase from the Dentists Register the name of Cartwright Davis, the address, the date of registration, and the description and date of qualification which they are satisfied have been incorrectly made.

Education and Public Health Committees.

The Council, on the nomination of the Irish Branch Council, appointed Sir Lambert Ormsby to succeed the late Sir Christopher Nixon as a member of the Education Committee.

Business Committee.

On the nomination of the Irish Branch Council Dr. Magennis was appointed to succeed Dr. Adye-Curran as a member of the Public Health Committee.

Indian Medical Service Examination.

Sir CHARLES BALL, as chairman of the Education Committee, presented a return on the examination for entrance to the Indian Medical Service held in July. The return stated that there were 17 candidates holding qualifications from 21 licensing bodies, of whom 15 received commissions. Only one was rejected. He failed in pathology and also to obtain the total qualifying marks. He was a graduate of an Indian University. Returns from the Royal Navy and the Army Medical Department had not been received since the last session.

The Apothecaries' Hall of Ireland.

Sir CHARLES BALL presented the report by the Examination Committee on the examinations held in the Apothecaries' Hall of Ireland, 1913–14, by Dr. J. Magee Finny. Sir Charles Ball, after the report had been received, moved:—

> That the General Council take into consideration the question of representing to His Majesty's Most Honourable Privy Council that the course of study and examinations to be gone through in order to obtain the qualification of Licentiate of the Apothecaries' Hall of Ireland are not such as to secure the possession by persons obtaining that qualification of the requisite knowledge and skill for the efficient practice of their profession.

He said that this motion, which was a recommendation of the committee, would not bind the Council further than the expression of its opinion that it was necessary to discuss this matter. The Examination Committee thought that the time had arrived when it was the duty of the Council to discuss the question. A great deal had been said about personal animus on the part of individuals and that kind of thing. All he could say was that the Examination Committee, which contained a large number of members who did not come from Ireland, had without the slightest dissent agreed to this recommendation that the General Medical Council should take this matter into consideration. The Medical Act of 1886 laid this duty upon them, and according to its terms if at any time the Privy Council thought that the General Medical Council had failed to secure the maintenance of a sufficient standard of proficiency in any examination, the Privy Council might intervene and carry out these duties itself.

Mr. VERRALL seconded the motion and remarked that the report made it necessary to undertake this consideration.

Dr. MAGENNIS said that he was the representative on the Council of the Apothecaries' Hall of Ireland, but in addressing it he was labouring under two difficulties. The first one was inexperience of the procedure of the Council, and the other was that this report by the Examination Committee had fallen upon him like a bomb thrown, not by the Germans, but by the Allies. He himself had given notice of a motion to the effect that the time had now come when any exceptional treatment of the Apothecaries' Hall of Dublin as regarded the inspection of its examinations and reports upon them should cease. He would desire to point out that the reports to the Council had shown that the Apothecaries' Hall was carrying out its duties. Let him read a few extracts from the reports of the examiners. In 1910 this appeared: "The whole of the examination may be considered thoroughly adequate and not inferior in any way to the examinations held by other licensing bodies." Another one was: "On the whole, the examination may be considered as satisfactory so far as testing the knowledge of the candidates is concerned. The candidates who were successful would have been equally successful with any other licensing body." In 1912 the assistant examiners expressed entire satisfaction with the manner in which the examinations were held. In 1913 it was stated that "The examinations were, in our opinion, sufficient: the supply of material was adequate, and the examiners were painstaking and conscientious." He went on to say that the Apothecaries' Hall was not afraid to meet the Privy Council on this particular matter, but he did not think it was an opportune time to bring forward such a matter as this. He sincerely hoped that the recommendation would not be approved of.

The PRESIDENT remarked that this was merely a recommendation that the Council should take up the subject. It was not a recommendation that they should approach the Privy Council.

Dr. MACKAY observed that the material in this report called for the most serious consideration on the part of every member of the Council. He thought, however, that time should be given to members of the Council to consider the report.

Sir CHARLES BALL, in reply, said that he had expected to have had a further report from the assistant examiners in surgery on the examinations of the Apothecaries' Hall of Ireland held since May, 1914, but it had not reached him from the printers. The Examination Committee found that there were inconsistencies between the report of the examiners and a table furnished by the Apothecaries' Hall. He thought that the Council should authorise the Examination Committee to transmit the report and the table back to the Apothecaries' Hall, and ask for their observations. Therefore, he did not think that there was any harm in postponing the matter.

The motion was carried by a large majority.

Sir CHARLES BALL then moved :—

> That the Irish Branch Council be authorised to appoint for a further period of one year a deputy to attend and be present on behalf of the General Council at the professional examinations held by the Apothecaries' Hall for the purposes set forth in Section 18 of the Medical Act, 1858; that the deputy so appointed present to the Council a report on the general character of such examinations; and that he be paid a salary of £50 for the year.

He said that the Examination Committee were quite convinced that these examinations should be carefully watched.

Mr. VERRALL seconded.

Dr. MAGENNIS moved as an amendment :—

> That the time has come when any exceptional treatment of the Apothecaries' Hall of Dublin as regards inspection of its examinations and reports upon them should cease.

The amendment was not seconded, and the motion was agreed to.

Sir CHARLES BALL then moved that the Examination Committee send their report which he had been unable to circulate to the Apothecaries' Hall with the request that that body might make any explanations which they would desire.

Dr. SAUNDBY seconded, and the motion was agreed to.

Public Health Committee.

Sir JOHN MOORE submitted a report by the Public Health Committee. It was in the following terms :—

> The committee again considered a letter dated Nov. 8th, 1913, from the Secretary of the Royal Institute of Public Health asking whether, in the opinion of the General Medical Council, that institute is a "recognised medical school" within the meaning of "Rule 3 [or] (2) (*i*)" of the rules adopted by the Council for Diplomas in Public Health; and, if not, asking the General Medical Council to add such words to the regulations as will remove any doubt which may arise as to the courses of lectures at the Royal Institute of Public Health meeting the requirements.
>
> The committee had consulted the legal adviser and had under consideration a Memorandum which had been submitted by him as to the general bearing of the questions raised in the letter from the Royal Institute of Public Health. An important Memorandum by the President on the subject was also before the committee. After full discussion it was proposed by Dr. Newsholme, seconded by Mr. Verrall, and unanimously resolved :—
>
> That under legal advice the committee is of opinion that the wording of the rule in question (Rule 3, or (2) (*i*)) does not admit of the inclusion of the Royal Institute of Public Health as a department of public health of a recognised medical school, and that no addition of words without a complete alteration of the rule can effect such admission.
>
> The Public Health Committee is further of opinion that no adequate reason has been shown for altering the present rule.
>
> Note.—Rule 3, so far as the above resolutions are concerned, reads as follows: Every candidate shall have produced evidence *either* (1) that, &c.; *or* (2) that, &c.
>
> Note 1.—...... Provided that if the candidate has (i.) produced satisfactory evidence that he has attended a course or courses of instruction in sanitary law, vital statistics, epidemiology, school hygiene, and other subjects bearing on public health administration, given by a teacher or teachers in the department of public health of a recognised medical school ...... the period during which he has been engaged in acquiring practical knowledge of his duties under this rule may be reduced to three months, to include an attendance on at least 30 working days.

The report was adopted.

Pharmacopœia Committee.

The PRESIDENT said that the Pharmacopœia Committee had no report to submit. They had sold 1834 copies of the Pharmacopœia last year.

Students Registration Committee.

On the motion of Dr. NORMAN MOORE the report of the Students Registration Committee was adopted.

Dental Education and Examination Committee.

Mr. TOMES submitted a report from the Dental Education and Examination Committee.

It contained the following passages .—

> 1. Attention has been drawn to the fact that the recommendations of the Council in regard to the curriculum of dental students are printed in two places—in a pamphlet bearing date June, 1914, and also in a leaflet printed for the information of the licensing bodies, but which is given to anyone who asks for it.
>
> It is unfortunate that in these two places the recommendations are not couched in identical terms, and this has given rise to inquiries as to their interpretation.
>
> But before dealing with the matter the Committee think it desirable to communicate with the several licensing bodies, as any redrafting of these recommendations may involve questions of importance. ......
>
> 3. An application from the University of Melbourne for the recognition of its degeee of D.D.S. has been received. The Acting Registrar has pointed out that he has not yet received any application for the recognition of their B.D.S. degree, and suggests that it would be convenient to take the two at the same time.
>
> 4. The committee have received for their information an Amending Act of the Province of British Columbia, March 4, 1914 :—
>
> BRITISH COLUMBIA, MARCH 4, 1914.
>
> This amends the Dentists Act. It institutes qualifying examinations. Institutes a Dental Council which, for disciplinary purposes, is empowered to associate with it a county court judge, and may subpœna witnesses and call for documents. It provides also for the payment of witnesses so called. There is an appeal from its decisions to the Supreme Court and a further appeal to the Appeal Court.
>
> Unqualified practice is prohibited by the Act, and practice is defined as the receipt of payment in any form for professional services. The unqualified employees of a registered dentist are brought within its scope, the employer being also concomitantly liable. Registered medical practitioners are exempted from the operation of the Act.
>
> The committee note with satisfaction that the prohibitory sections are directed against the act of practice and do not merely prohibit the improper assumption of title.
>
> HONG KONG ORDINANCE, 1914,
>
> was communicated by Colonial Secretary, who invites observations. It establishes a Register and an Advisory Dental Board. It does not establish any form of diploma, but leaves large discretion to the Governor in Council in the recognition of grounds of admission to the Register, such as long practice in the colony, or other grounds deemed sufficient. Practice, or the offer to practice, or the wrongful assumption of titles are prohibited under penalty. Unsuccessful attempts at legislation were made in 1905, the difficulty being the small number of practitioners holding any qualification and the large number of Chinese practitioners. A reasoned report upon the measure is tendered by the local Attorney-General, who regards it as the best compromise attainable under the circumstances obtaining in the colony.

The report was adopted.

Dr. NEWSHOLME moved :—

> In view of the large amount of practice of dentistry by unqualified persons, and of the fact that the number of dentists on the Dental Register has not increased since the Register was formed, the several licensing bodies be asked to make suggestions of any modification or curtailment of the curriculum which may be desirable without lowering the standard of dental practice.

He said that he brought forward the motion for the following reasons. Reference to the Dental Registers showed that in 1878 there were 5289 dentists registered. In 1914 there were 5275. After making allowance for the large numbers of dentists who were admitted to the Register because they were in practice in 1878, those figures could not be regarded as satisfactory. There should not have been any decrease in the number of registered qualified dentists in this country. During the last 30 years the population of the United Kingdom had increased by nearly 30 per cent. From 1889 to 1912 the number of medical men had increased by about 46 per cent, and in these circumstances the lack of increase on the part of dentists was very remarkable. The demands for dental treatment had increased. It was a notorious fact that the number of unqualified and unregistered dentists exceeded the number who were qualified. That was most serious from the dental point of view and therefore from the point of view of public health. It was necessary in these circumstances to look into matters in order to see whether some improvement might not be required. He was not sure whether any modification of the curriculum would commend itself, and for that reason his motion was framed merely to obtain an expression of opinion from the licensing bodies whether any modification of the conditions might be practicable without lowering the standard. The Council by resolution had laid down what was a standard curriculum of four years. He had no fixed opinions in regard to the allocation of time in the curriculum, but it was important in the public interest that the whole subject should be inquired into, and also whether the four years' curriculum was necessary. He thought that in the first place the Council should ask the licensing bodies whether any modifications might be made without injury to the professional standard.

Mr. VERRALL seconded. He remarked that many medical men felt very much the shortage of dentists.

Dr. MACKAY remarked that the motion raised a grave question, but the modification of the curriculum was also a very serious matter. In his view the Council was not in a position to come to a decision on a question of such importance, and it would be only proper that this proposal should be remitted to the Dental Education Committee for report.

The PRESIDENT said that the motion introduced quite new matter, and no notice had been given that it would be raised. He thought that the proper course would be for the Council to refer the motion to the Dental Education Committee for consideration.

Mr. TOMES observed that the committee would accept the principle that inquiry was desirable. But he would point out that the number of qualified men on the Register had increased, and these men were taking the places of those who had obtained registration owing to the fact that they were in practice in 1878. The numbers of those seeking qualifications were not so great as he would have liked to see. The increase was insufficient. Whilst he was ready to consider what was in the motion he doubted whether the severity of the curriculum very largely affected the question. What more largely affected the question was the weakness of legislation.

Dr. Norman Moore considered the question raised by the motion as urgent.

Dr. Caton agreed that this was clearly a matter of the greatest importance, particularly in the provinces. When a portion of the public saw the vast increase in the numbers of the unregistered practitioners it was beginning to think that there was not much difference between the registered and the unregistered practitioner. He thought that the Council might consider as a temporary expedient a slightly lower standard. But the profession should take steps to obtain the reversal of the most unfortunate decision in the House of Lords some years ago.

Dr. Norman Walker suggested that if the Dental Education Committee could arrange to make inquiries in the meantime, the Council might consider the matter at its next session.

The President remarked that the Council might be able to do much more by giving the matter very full consideration.

Dr. Macdonald suggested that the motion should not be pressed. If that were done, he would move :

> That the motion should be referred to the Dental Education and Examination Committee for consideration, and that it have power to communicate with the licensing authorities on the subject.

Dr. Newsholme said that he had no desire to reduce the standard of dental education. He was prepared to accept Dr. Macdonald's suggestion as an alternative to his, on the understanding that the Dental Education Committee should make inquiries in the interval in order to elicit the facts and the opinion of the licensing bodies.

The motion of Dr. Newsholme was not pressed, and the Council adopted as a resolution the suggestion of Dr. Macdonald.

Unqualified Practice Prevention Committee.

Dr. Langley Browne submitted a report of the Unqualified Practice Prevention Committee. That report enumerated the recommendations of the Select Committee of the House of Commons on the subject of Patent Medicines. The Unqualified Practice Prevention Committee recommended—

> (*a*) That the General Council should convey to the Lord President of the Privy Council an expression of its complete approval of the recommendations of the Select Committee.
>
> (*b*) That the General Council represent to the Government, through the Lord President, the necessity for the immediate creation of a Ministry of Public Health, in pursuance of the recommendations of the Select Committee.

The Council formally adopted these recommendations.

Conclusion of Session.

On the motion of Dr. Norman Moore, the President was thanked for his services in the chair. The session then came to an end, and the Council rose to meet again in May, 1915.

HEALTH OF THE METROPOLITAN POLICE.

Appended to the report of the Commisssoner of Police of the metropolis (Sir E. Henry, G.C.V.O., K.C.B.) for the year 1913, is a report on the health of the force by the Surgeon-in-Chief, Mr. Charles A. Ballance, M.V.O., F.R.C.S. The latter states, *inter alia*, that the strength of all ranks on Jan. 1st, 1913, was 20,286, and on Dec. 31st, 1913, 20,844, giving as the mean 20,565. The daily average number of men on the sick list was 482·14 and the average daily number on sick leave 41·96. The average daily loss on the whole force by sickness showed a percentage of 2·85 as against 2·41 in 1912. In reference to this apparent increase the Surgeon-in-Chief observes that "there is no real increase of sickness. The reason the figures are higher is that after operations and after severe, and even slight, illness, longer periods of leave have been granted than formerly. A substantial period of sick leave is necessary in order to ensure the attainment of complete convalescence. An officer after operation or illness must be truly fit to stand the strain of duty at the present time. The good effects of longer periods of leave will be seen in the coming years. Health will be maintained and officers will be able to perform more efficient and longer service." The total number of police on the sick-list during the year on account of injury was 1926—viz., 1121 on duty and 805 not on duty. The number of police known to have been admitted into the general hospitals and infirmaries of the metropolis on the recommendation of the chief or divisional surgeons was 399, of whom 21 died. There were also 39 admissions to cottage hospitals, of whom 1 died, and 196, of whom 4 died, were admitted into special hospitals and sanatoriums. 663 officers were sent to convalescent homes for periods varying from 7 to 65 days. Fourteen men were admitted to workhouse infirmaries for observation, one of whom died, and 7 were certified insane and sent to asylums. The following is a table of the number of cases seen and operations performed by the dental surgeons:—Cases seen, 657; visits paid by police, 1189; extractions, 2950; fillings, 372; other treatment given, 205; local anæsthetic used, 739; "gas" administration, 27. There were 43 bacteriological examinations for tubercle bacilli and 22 for diphtheria bacilli. The number of police holding, on Dec. 31st, 1913, certificates of competency to render first aid was 16,284. There were 67 cases in which the police were specially commended for first aid rendered. The number of police injured whilst in the execution of their duty during the year was 2953, of whom, however, only 615 had to be placed on the sick list. In 1729 cases the injuries were caused by drunken prisoners and in 809 cases by other prisoners. There were 88 cases in which the injuries were caused by dog bites. In addition to the foregoing, 727 police were accidentally injured whilst on duty. Of these, 389 were injured by falling down or slipping in the streets or when examining premises, 28 by being kicked by horses, 12 by being trodden upon by horses, 124 while riding bicycles, 11 by bicycles ridden by other persons, 10 in testing or driving motor vehicles or boats, 18 by motor vehicles, 23 by objects falling, 9 by foreign objects entering the eye, 8 at fire drill, other causes 95.

Royal Albert Hospital, Devonport.—The annual meeting of the subscribers to the Royal Albert Hospital was held on Nov. 21st, under the presidency of the Bishop of Exeter. The medical report stated that for the 12 months ended Sept. 30th last the in-patients numbered 703. The financial statement showed the expenditure was £4254, being £985 in excess of the income. The committee draw attention to the serious financial position of the charity, and state that unless greater support is extended they will have to realise some more of their investments.

Scarcity of Doctors in Ireland.—At a meeting of the members of the Lurgan board of guardians held on Nov. 26th it was stated that no applications had been received for the post of resident medical officer. The salary offered was only £80, while in Belfast it was reported that the guardians were giving a resident doctor £120. A committee was appointed to consider the question of increasing the salary. The scarcity of medical men in Ireland is due partly to the fact that many are at the front, but also doctors on the panel in England are now giving larger salaries than formerly for assistants.

Reuben Harvey Memorial Prize.—The eleventh award of this triennial prize will be made on July 1st, 1915. The competition for the prize is open to all students of the various schools of medicine in Dublin which are recognised by the medical licensing bodies in Ireland, and also to graduates or licentiates of these bodies of not more than three years' standing at the time of the award. The prize, value £25, will be awarded to the writer of the best essay, on a subject to be selected by the candidate, evidencing original research in animal physiology or pathology; the essay to be illustrated by drawings or preparations. The essays, bearing fictitious signatures, are to be lodged with the Registrar of the Royal College of Physicians of Ireland, Kildare-street, Dublin, on or before June 1st, 1915.

THE LANCET.

LONDON: SATURDAY, DECEMBER 5, 1914.

The Research Schemes of the Medical Research Committee: the Influence of the War.

THE Medical Research Committee established under the National Insurance Act have now formulated their schemes for research, and the details of these schemes are appended to a letter explaining their general design, which has been addressed by Lord MOULTON of BANK, as chairman of the Medical Research Committee, to Mr. MASTERMAN, chairman of the National Health Insurance Joint Committee. The schemes have been officially approved and will now be acted upon, save where the exigencies of war have necessitated modifications. The proposal of the Governing Body of the Lister Institute to offer the Institute to the nation as a nucleus towards a National Institute of Medical Research was still before Lord MOULTON when writing the letter, but in the event of this amalgamation not occurring no change of programme would be imposed upon the Medical Research Committee, who were prepared to proceed to the equipment of the Mount Vernon Hospital, the buildings of which were recently acquired. We have already announced the appointments made to the staff of the National Research Institute, but we may remind our readers that they are as follows:—Bacteriology, Sir ALMROTH WRIGHT, assisted by Captain S. R. DOUGLAS; Applied Physiology, Professor LEONARD HILL, assisted by Professor BENJAMIN MOORE and Dr. MARTIN FLACK; Bio-Chemistry and Pharmacology, Dr. H. H. DALE, assisted by Dr. G. BARGER and Dr. A. J. EWINS; Statistics, Dr. JOHN BROWNLEE. Dr. W. M. FLETCHER, D.Sc., lately demonstrator of physiology in the University of Cambridge, is the secretary of the Medical Research Committee, whose office is at St. Stephen's House, Westminster, S.W.

The plan of future work, as foreshadowed in Lord MOULTON'S beautifully distinct communication, appears to us of the greatest promise. It is clear that provision is made for strong central control, as is necessary where public funds are concerned, but arrangements are also defined for the distribution of those funds, so that instead of their employment only, or even principally, in a central institution, the various problems of pathology and bacteriology will be attacked under public subsidy at all the principal scientific centres in England, Ireland, Scotland, and Wales. The different schemes have been carefully thought out, members of the Medical Research Committee having visited most of the selected centres, where they have received full assistance from the heads of the laboratories, showing that all apprehension has been removed that the provinces and the Scottish, Irish, and Welsh scientific institutions would have no proper lot in the developments of research projected. The cordiality of the heads of the laboratories has been secured by, among other things, the judgment with which the Committee have endeavoured to assign particular inquiries to particular research centres in accordance with the local facilities or the personal predilections of the directors. It will be the duty of the Medical Research Committee to correlate the results obtained, and to one wise and broad-minded decision of the Committee we wish to draw particular attention. Lord MOULTON states that he and his colleagues "are strongly of opinion that grants for personal remuneration to a scientific worker should be clearly distinguished from those made to meet laboratory or other expenses." To those who have conducted researches in return for Government or other grants this expression of opinion will have great significance, for it has too often happened that the workers have been actually out of pocket by their labours, being compelled to spend in the acquisition of special information a sum as large as or larger than that placed at their disposal. Lord MOULTON exposes the situation from the other side, pointing out that, in the absence of a distinction between remuneration for services and money paid for expenses, the temptation towards a dangerous reduction of expenditure would be present. This is so, and such frailty must be reckoned with, but scientific workers have much more often required protection from the tendency to spend their own money than from the tendency to save the money of others.

In a second direction the Committee have shown an intimate acquaintance with the difficulties of coöperative research work and have quietly dealt with them by the brief statement that the results of all this original work will not be permanently buried in the form of reports to the head of a department. The Committee propose that liberty shall be given to the workers who are aided from the National Medical Research Fund, and who are of a status to have independent work committed to them, to publish their results through the technical scientific journals. Workers under the direction of a professor, or under the head of any laboratory who is responsible to the Committee will be required to obtain the consent of their individual directors, but furnished with this the same liberty to publish their work will be accorded to them. On their side the Committee reserve the right to republish the results in any form where their issue would assist in the coördination of work done, or would indicate directions for work remaining to be done. A carefully thought out estimate of cost is appended to the schemes, and shows that the expenditure for the year 1914 leaves an unassigned balance of £10,000, an economy which is very desirable in view of the special pathological work which may shortly be needed in connexion with the war. And here it should be pointed out that the amount at the disposal of the National Medical Research Fund for 1914—namely, £56,500—is greater perhaps by £5000 than can be anticipated for 1915. For the Fund represents a capitation fee of 1*d.* paid by the Government for each insured person, and the number of insured persons next year will probably not be so great. It is well that the source of the Fund should be remembered, as the public appears to think that the insured persons supply the Fund.

A description of the emergency work that has been done already by the National Medical Research Fund in connexion with the war is affixed to Lord Moulton's letter. The inoculation department of St. Mary's Hospital, and with it the clinical facilities which Sir Almroth Wright enjoys, had been secured, together with Sir Almroth Wright's services, under the National Research scheme for the year from Oct. 1st, 1914, by an arrangement with St. Mary's Hospital, while by the summer of 1915 it was hoped that the Mount Vernon building would be transformed into a hospital for research purposes. But owing to the war this building has now been placed at the disposal of the War Office, and is fully occupied and staffed with a view to the treatment of the wounded. An option has accordingly been obtained from St. Mary's Hospital permitting the extension for a second year of the temporary arrangement with the Medical Research Committee. In the meantime permission has been given to Sir Almroth Wright and Captain Douglas to devote the whole of their time to the preparation of vaccines for the use of the forces, an enormous quantity of vaccines has been prepared for the Admiralty and the War Office at the Inoculation Department of St. Mary's Hospital, and Sir Almroth Wright has been appointed consultant physician to the forces overseas. At home the Medical Research Committee, with the cöoperation of Sir Alfred Keogh, are making arrangements, wherever practicable, for the proper bacteriological investigation of infected wounds at the chief military hospitals, and have also undertaken the compilation of the medical and surgical statistics of the war.

Vaccination.

Most of us must sometimes have wondered how far the vaccination of infants affects the type and epidemic periods of small-pox in this country, and to what extent our protection against epidemics in future will be influenced by the diminution which is taking place in the systematic vaccination of children. As a matter of history, the general adoption of infancy vaccination produced a marked change for the better in the epidemiological facts of small-pox; the disease ceased to be endemic, generally prevalent, and often fatal amongst children, and became rarer in its visitations and more and more one from which the principal sufferers who remained were adults. It does not necessarily follow, however, that under modern methods of dealing with small-pox reversion to an unprotected child population would entail reversion to eighteenth century prevalence. Again, it is beyond question that the protection of infancy vaccination, which as regards attack continues for several years, and as regards severity of illness lasts well into adult life or even to advanced age, has been priceless in past decades, when the population was running relatively large risks of exposure to infection. But looking at more recent experience, can this protection be considered so important a factor now that epidemics are so far apart and our health authorities, with the aid of emergency vaccination, can deal with them confidently and certainly when they arise? Such questions, of course, owe most of their importance to the purely artificial position brought about by legislation. Parliament has never attempted to prevent epidemic small-pox by vaccination. Had it done so the law would have required general and compulsory re-vaccination, or, if only a single vaccination could be insisted upon, it would at least have shifted the compulsory age to young adult life, as has often been proposed. Since the first Vaccination Act all official systems of vaccination have related, with greater or less efficiency, only to the vaccination of the infant, and have been determined quite as much by political as by medical or epidemiological considerations. So far as these systems have promoted vaccination they have consistently received support from medical opinion, and when regard is had to the many thousands of people who have owed their escape from attack by small-pox to their vaccination in infancy, and to the many others who owe to the same cause the fact that when attacked by small-pox they have not suffered severely or been seriously disfigured, medical action in the matter has been justified and fruitful for good. But meanwhile outbreaks of small-pox when they occur are dealt with by an increasingly efficient system applicable alike to those who have been vaccinated in infancy and to those who are unprotected. Epidemics are kept under by administrative measures which secure the prompt detection of cases and their removal to hospitals where they are surrounded by well-vaccinated persons who do not—it would be no exaggeration to say who cannot—contract small-pox, and are there kept till their infectiousness is over. Those who have been in contact with the cases before isolation are sought out, watched, and vaccinated wherever possible, any who develop small-pox being treated at the earliest possible moment in the same way as the first cases.

The system has steadily developed and many circumstances have combined to produce its continual improvement. The fact that small-pox hospitals have themselves been associated with the spread of small-pox when placed in populous neighbourhoods has been recognised, and properly isolated sites are now chosen. The system of compulsory notification, the interchange of notifications between health officers, the telephone, the motor-car, and all that these imply, have made the tracing of contact and suspected cases possible in a way neither imagined nor imaginable 20 or 30 years ago. The staff available in our local health departments has grown in numbers and efficiency, while vaccine lymph can now be made and stored in practically unlimited quantity and be supplied at the shortest notice. As finality in these methods has not yet been reached, and other improvements will no doubt be made, it has now become quite arguable that administration on present lines should suffice to keep epidemic small-pox within small dimensions, whether the country has been well vaccinated in infancy or not, and that so long as administration remains good and people consent to be vaccinated in emergency, systematic vaccination may cease without serious consequences. This is no doubt the popular view, and its danger, paradoxically, lies in the fact that a good deal can be said for it. It must be remembered that even the best schemes of administration may break down, and should the breakdown occur with small-pox in a virulent phase, an 1871 type of small-pox for example, the result among a totally unprotected community may be much more serious than that of any local breakdowns of which we have had recent experience. As the behaviour and occurrence of small-pox is full of surprises, it is only fair that parents should be encouraged to protect their children from risk, while the more children and adults there are in the population who possess the protection of vaccination and revaccination the better the security of the community against small-pox and the better for the individuals who are protected. For such reasons we think most medical men would say that notwithstanding altered conditions of recent years, it would still be advisable for the State to strengthen its vaccination laws, or if politically this is impossible, at least not to weaken such methods as remain for promoting systematic vaccination.

At the present moment it is useful to indicate in such obvious terms as the foregoing the position of medical science to some modern aspects of practical vaccination problems; and a book which has just appeared, written by Dr. C. K. MILLARD, the medical officer of health of Leicester, calls for notice in this connexion.[1] In some respects Dr. MILLARD takes what we believe is an exceptional view of the vaccination question. He would do away with systematic infancy vaccination as soon as possible, arguing that though it may be good for the individual it is actually prejudicial to the community, as it results in the presence among adults of cases of small-pox which are so mild that they are not easily recognised, and consequently go about and spread infection. We are not sure that this contention is complete on its epidemiological side. Previous vaccination or previous small-pox are not the only causes of mild and scarcely recognisable attacks of the disease. In epidemics of certain types, such as those which have lately occurred in the United States and in Australia, the infection is so attenuated that an abundance of very slight cases has been found among the unvaccinated. If Dr. MILLARD'S argument were sound, however, it would still hardly constitute a sufficient reason for advising a parent that his child should not be vaccinated; the whole force of the argument to be placed before him lies in the power of vaccination to protect the individual. On these and other matters the contentions and speculations in the volume are worth study and reflection. The reader, however, must be prepared to find scientific questions mingled with a considerable dose of provincial vaccination controversy, and if he is to get pleasure from his author he will have to enter into and appreciate the latter's pose. This is the position of the just man—we had almost written the only just man—to whom insight has been given to see the "vaccination question" in its true perspective, and to balance between those who are called "pro-vaccinists" and "antivaccinists." In these matters the hero of the book is a special conception of Dr. MILLARD, an antivaccinationist free to carry on all his propaganda against vaccination, if only he will admit that vaccination has a protective value against small-pox. As most antivaccinationists spend their time in contesting this very point, the position is occasionally a little bewildering, and by those who have no great interest in the antivaccinationist the balancing process may be found a little tedious. After all, it has been the "pro-vaccinist" doctor and not the antivaccinationist who has called in the resources of modern science and invention to aid in the suppression of small-pox, and it is hardly reasonable that every one of the doctor's actions which does not involve the inoculation of lymph should be put in the scale to weigh "against vaccination."

HEALTH OF CORNWALL IN 1913.—The medical officer of health of Cornwall in his annual report for 1913 states that the general death-rate was 11·85 per 1000, the lowest on record. The infant mortality was 91·77 compared with 84·01 in 1912. There were 414 deaths from pulmonary tuberculosis, being a rate of 1·25 per 1000 living, which Dr. R. Burnet considers high for an agricultural county. The deaths from "miner's phthisis" in 1911, 1912, and 1913 totalled 386. The medical officer of health alludes to the insufficient number of isolation hospitals in Cornwall, and states that although 1990 infectious cases were notified only 41 were treated in isolation hospitals.

Annotations.

"Ne quid nimis."

WAR AND THE QUALITY OF THE FOOD SUPPLY.

IN some directions during the time of war there will be temptation to introduce on a large scale cheap substitutes into foods. The practice of substitution has become a fine art, and the analyst admits to-day that his methods of detection cannot always claim precision. In normal times, in fact, we know that the practice of substitution is rife, but at a time of war there is sure to be a survey made by certain manufacturers as to the articles of food which can be used to replace those which threaten to become scarce or dear. In many cases such a substitution is quite legitimate on dietetic grounds so long as the purchaser is not misled. The use of glucose syrup, for example, in the place of sugar for sweetening and other purposes does not rob the original formula for the preparation of its energy value. When it is considered that before sugar can be digested it has first to be converted into glucose in the alimentary tract, no objection can be raised to the substitution of glucose for cane or beet sugar. The deceit, when practised, is not of serious dietetic import; but when cane sugar is expected in a preparation it should be obtained. A correct description on the label would of course save any misunderstanding in this matter as between the seller and the purchaser. It is a pity in some respects that glucose cannot be economically prepared for commercial purposes in crystalline form, but even then it would attract moisture too readily for practical use. Every degree of increased taxation on beer will no doubt lead some of the trade, at all events, to attempt to cheapen the production of the fluid, and here is a well-known field for the use of substitutes. It may be remembered that the brewer is not taxed on the alcoholic strength of his beer, but upon the measure of its gravity. It is, in fact, a malt tax rather than an alcohol tax, and is applied equally to malt beverages which may be non-alcoholic. The heavy gravity beers pay the highest toll, and we may expect that further attention will be directed to the increased output of weaker beers, and there may be a greater recourse to the use of substitutes—e.g., cheaper grain, maize and rice, and possibly bitters other than hops. Margarine, now so largely made from nut oils, a very large supply of the refined article being supplied by Germany, may possibly increase in price, though the supplies of genuine butter are not likely to diminish greatly. Our supplies of butter come, as is well known, from Denmark, Holland, France, and our colonies. It would be a curious and remarkable position, and not without the bounds of probability, if the chief cheap substitute for butter—namely, margarine—became dearer than butter itself. Here, again, there would be no loss sustained in actual dietetic value, because margarine is so carefully prepared now that there is very little reason for believing that it is less wholesome or less nutritive than its prototype. Many substitutes are as a matter of fact perfectly wholesome, and replace satisfactorily from a dietetic point of view the genuine article, but we hold that on no grounds can substitution be permitted unless the purchaser is made aware of it. In time of war the public should be protected just as effectually as in time of peace against dishonest dealing, and when increased temptations exist the administration of the Sale of Food and Drugs Act should be especially alert.

THE OPERATIVE TREATMENT OF SEVERE GASTRIC AND DUODENAL HÆMORRHAGES.

A STRONG plea for the conservative and expectant treatment of patients with bleeding gastric or duodenal ulcers is made by Lindberg,[1] who deprecates hasty surgical interference in these cases. His attention was particularly directed to the matter because he saw five fatal cases of hæmatemesis from gastric ulcer within a year; three of them were admitted to Faber's clinique at Copenhagen within the space of a fortnight. This led Lindberg to look into the statistics of the cases of gastric ulcer treated in this clinique between the years 1896 and 1914. He found they numbered 550, and in 68 of these the hæmorrhage was dangerous to life, amounting to a litre (1¾ pints) or more. All were treated on medical lines, but only 5 of the 68 died as a result of the loss of blood, a mortality of 7·3 per cent. He states his belief that surgical interference would have been powerless to save any of these five lives. Passing on to the published results of the surgical treatment of hæmatemesis, he is driven to the conclusion that they have hitherto proved far less favourable, and notes that the first operation to stop gastric hæmorrhage was performed in the year 1887 by Mikulicz. Various operations have been performed in these cases, and the following table, borrowed from Kraft (1910), sets out roughly their nature and the results they have yielded:—

Operation.	Cases.	Deaths.	Mortality per cent.
Gastrotomy	7	5	71
Gastro-entero-anastomosis	30	14	47
Cauterisation	6	3	50
Excision	23	5	22
Ligature	17	3	17
Total	83	30	37

It is true that the statistics do not make it plain how far the operations were indicated by single large or repeated small hæmorrhages, but Lindberg argues that the point is not one of great importance. Kraft himself gave an account of five cases in which the bleeding gastric ulcer was located by the use of Rovsing's gastroscope, an instrument that may prove to be of service in the treatment of these cases; two of the five patients died, and in a later communication (1912) he detailed two further cases treated surgically, both with a fatal result. Lindberg therefore advises that acute cases of dangerous gastric or duodenal hæmorrhage should always be treated medically. Stimulants of all sorts, and particularly intravenous injections of saline solution, should be avoided, as they raise the blood-pressure and lessen the tendency of the blood to clot. Should the patient become collapsed the foot of his bed may be raised on blocks. The hypodermic injection of morphine is contra-indicated; for while it gives the patient immediate relief, it often seems to promote further hæmorrhage—perhaps by preventing spasm of the gastric musculature and the tendency of such spasm to constrict the vessels in the gastric wall. On the other hand, Lindberg warmly recommends the use of subcutaneous injections of sterile gelatin in 10 per cent. solution. The dose is 40 c.c., given at a temperature of 40°C., and repeated at least once a day. Nutrient enemas and small quantities of milk by the mouth may be administered, or a few days of absolute starvation may be ordered. He also speaks well of Bourget's practice of washing out the stomach daily with 100 c.c. of 1 per cent. ferric chloride solution, the patient lying supine first and later prone; the solution is afterwards removed from the stomach by aspiration through the soft sound by means of which it was introduced. In the case of patients with repeated small hæmorrhages from gastric ulcers, particularly if they fail to recover from the resulting anæmia in the intervals between the attacks, Lindberg is inclined to advise surgical interference, with the proviso that the operation should be performed *à froid*, or when the patient is not acutely ill.

THE CLINICAL ESTIMATION OF DIASTOLIC BLOOD PRESSURE.

IT has been recognised for some time that systolic blood pressure estimations give only partial evidence of the circulation; the diastolic pressure is at least of equal value, and only a combined knowledge of the two factors can give an approximate idea of the cardiac activity. The practical difficulty of gauging diastolic pressure has been considerable, and even the later French oscillation instruments, such as Pachon's, do not give wholly satisfactory results. It seems, however, that we have at last got a reliable method and one, too, of ready clinical application. This is the auditory method of McWilliam and Melvin. The fullest details of this method, together with the many careful experimental data upon which it is founded, are recorded in *Heart* (1914, v., 153), but other papers dealing with the same subject and by the same group of workers have appeared elsewhere. The only instrument wanted is the ordinary Riva-Rocci sphygmomanometer, or any of its modifications, and a stethoscope. The armlet of the instrument is applied to the upper arm, and in such a way as to leave a space between its lower margin and the bend of the elbow. Over the brachial artery at this situation the stethoscope can be applied. The systolic pressure may be measured in the ordinary way, the height of the mercury being read off at the moment when the added pressure has obliterated the radial pulse. The stethoscope applied over the brachial artery now fails to register any sound. On slowly relaxing the pressure and still listening with the stethoscope, it is curious to find that the pulsations can be heard. Normally over any artery no sound can be made out. The sounds vary in character and loudness with the falling pressure, and four stages can be recognised. These are (1) sharp, clear sound; (2) muffled or murmurish; (3) loud and clear; (4) dull; and (5) abolition of sound. The important transition to note is when the loud and clear sound gives way to the dull fourth stage. This gives the diastolic pressure. This transition is described as abrupt and definite, and we can certainly confirm this observation. Were it not so, indeed, the method would give little help. Sometimes the abrupt dulling practically coincides with abolition of all sound; often, however, the dull sound can be heard even though the pressure is still further lowered. Abolition of sound, in fact, is not the key for the diastolic pressure as was at one time supposed. This, then, is the auditory method. In one class of case only does it fail, that is in aortic disease, for here even in absence of any vessel constriction a murmur may be heard. The results of this method are of interest. A series of 51 cases of various kinds were examined by Dr. G. S. Melvin and Dr. J. R. Murray in the *Quarterly Journal of Medicine* (1914, vii., 419). The range of diastolic pressure is wide, from 150 mm. Hg to 50 mm. This is a much wider range than that found in the normal, 82 mm. to 50 mm. The pulse pressure, or the range between systolic and diastolic pressures, has also a wider range than in normal controls, 163 to 26 mm., as compared to 73 to 22 mm. Oscillatory diastolic estimations show similar variations, but comparison between the two methods shows discrepancies, the balance of accuracy, however, being with the auditory method. There is little doubt that observation by this method will modify our views on some aspects of blood pressure, not its least value being its ease of clinical application.

THE ORDER OF ST. JOHN OF JERUSALEM.

A PARTICULARLY fascinating little book at the present juncture is "Chivalry and the Wounded," which contains a historical account of the Hospitallers of St. John of Jerusalem (1014–1914), by E. M. Tenison.[1] The St. John Ambulance is well known to the public, but the fact that it owes its origin to the modern successor of one of the old orders of chivalry is perhaps less generally realised. The author describes in the first two chapters the foundation of the hospital in Jerusalem for the succour of travellers, exactly 900 years ago—viz., in 1014—and the organisation of the Knights Hospitallers after the capture of Jerusalem in 1099 into a regularly constituted religious order, which was formally recognised by the Pope in 1113. In 1291 the Knights of St. John in Palestine sent the women and children in the galleys of the Order from Acre to Cyprus, and with the Red Cross Knights Templars defended Acre to the last against the hosts of the Sultan, only a small number under the Grand Master, Villiers, effecting their escape to Cyprus, where the Order established a new home, transferred in 1310 to Rhodes. They were driven thence by the Sultan Solyman in 1522, and after being homeless eight years established themselves in Malta in 1530, where they remained until 1798. Meanwhile, about 1102, a branch of the Order had been established in England, with headquarters in Clerkenwell, where the hospital gate is still standing, and forms the headquarters of the present priory of the Order. Henry VIII. suppressed the Order and confiscated its property, and in 1548 under Edward VI. its priory was blown up. A brief revival occurred under Mary, but Elizabeth desecrated it by conferring the priory on her Master of the Revels. In 1798 its Maltese stronghold supinely submitted to General Bonaparte, when resistance for only a few weeks would have brought the British navy under Nelson tc their relief. Von Homspech, the sixty-ninth and last Grand Master of the Order, whose supineness had led to the disaster, died in 1805, a poverty stricken member of a religious community at Montpellier. The last chapter describes the revival in 1831 as a lay community of the English Order of St. John, which devoted itself to the relief of the sick and helpless, the support of cottage hospitals and convalescent homes, and the establishment in 1871 of the St. John Ambulance Association. There are branches of the Order also in Austria, Germany, and Spain. The book closes with an appeal to the nation for funds to help the Order to meet the strain of the war, in which it is doing splendid work through its mobilised hospital orderlies and upwards of 130 highly trained nurses serving at the front.

THE SHADED LAMP IN SHOP WINDOWS.

A WORD of warning seems just now to be necessary in regard to the shading of incandescent electric lamps in the shop windows. The regulations requiring less light to be employed in the shops are in many instances complied with by simply wrapping round the upper part of the bulb some coloured or darkened paper. This method has its risks, inasmuch as the glowing filament gives off considerable heat, and when this heat is jacketed by an insulating substance the point of ignition may easily be reached. If an electric lamp be buried in cotton-wool the wool soon commences to scorch and ultimately to burst into flame. With a free circulation of air round the lamp there is little danger. There may be seen now in London, however, many very profusely dressed shop windows full of inflammable goods, and in the midst of them all, electric lamps are suspended partly wrapped in a paper shade. When the windows, as they soon will be, are heavily dressed with Christmas goods, the risk will be obviously increased. This is no time for promulgating scares, but we have actual evidence of a paper shade being fired in the way described, and we therefore write seriously on this matter in order that a real risk may be avoided. There seems to be some idea that because an electric filament is enclosed in a glass bulb and is not flame it is free from the possibility of setting other things on fire. That is not the case.

THE FRIEDMANN "CURE" FOR TUBERCULOSIS.

GERMAN traders have taken their wares to every land, and if they fail it is not for want of advertisement. In the same way certain of their medical specialists have been entrusted with missions to less fortunate lands, particularly America. The "twilight sleep" campaign of Professors Krönig and Gauss, who crossed the Atlantic to offer the women of America—for a consideration—the advantages of painless labour, was materially assisted by articles in the lay magazines and daily papers, for which, it is fair to say, the distinguished gynæcologists disclaimed all direct responsibility. But an even more notorious effort of the same kind was that of Dr. Friedmann, of Berlin, who went to New York a year or two ago with a tuberculin which was going to abolish tuberculosis. People crowded to the offices which Friedmann rented for the purpose, and the affair attained such publicity that the United States Government thought it worth their while to appoint a commission to inquire into the validity of the claims put forward. This commission has just reported, and bases its conclusions on a study of 94 cases of tuberculosis treated with the Friedmann remedy, a tuberculin made from living acid-fast bacilli which were said to inflict no injury in spite of their being alive at the time of injection. A more damning reply than that which the commission has furnished it would be impossible to conceive. It reports that the curative material has certain deleterious effects, which are especially likely to be manifested in tuberculous subjects; that its favourable influence on tuberculous processes is at best slight and uncertain; and that the organism used in the preparation of the vaccine is by no means proved to be a tubercle bacillus at all. The commission sums up as follows: "The claim of Dr. F. F. Friedmann to have originated a specific cure for tuberculosis is not substantiated by our investigation. The claim of Dr. F. F. Friedmann that the inoculation of persons and animals with his organism is without harmful properties is disproved." In fairness to his Berlin colleagues it must be remembered that they did not support Dr. Friedmann's claims, and we are glad to think that in THE LANCET they were rated at their right value from the beginning.

THE Bradshaw Lecture will be delivered in the theatre of the Royal College of Surgeons of England by Sir Frederic Eve, on Tuesday, Dec. 15th, at 5 P.M. precisely. The subject of the lecture will be Acute Hæmorrhagic Pancreatitis, with remarks on the Etiology of Chronic Pancreatitis. Fellows and Members of the College are invited to attend. Students and others who are not Fellows or Members of the College will be admitted on presentation of their private visiting cards.

ON Monday next, Dec. 7th, at 8.30 P.M., a discussion will take place at the Medical Society of London on Tetanus, with special reference to (*a*) prophylaxis; (*b*) the serum treatment of established tetanus—dosage and method of administration. The discussion will be introduced by Dr. D. Embleton, who will be followed by Professor F. W. Andrewes, Dr. John W. H. Eyre, Dr. R. B. Blair, Dr. Carl Browning, and others.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

NUMEROUS additions have been made to the Committee during the week, and promises of support have been received. Those who desire to join the Committee responsible for the collection and distribution of the Belgian Doctors' and Pharmacists' Relief Fund are asked to signify their intention promptly, as the lists will soon be printed.

Through the British committee the necessary steps have now been taken for the despatch to Brussels of the packets of medical material which had been approved of by a subcommittee appointed to arrange this matter.

The chairman, secretary, and treasurer of the Committee attended a meeting of the council of the Pharmaceutical Society, by invitation, on Tuesday last, when Sir Rickman Godlee made a brief statement of the work so far done by the Committee and of its intentions for the future. Several members of the council of the Society inquired as to how far any packets of medical material sent over to Belgium could be safeguarded from the enemy in occupation, and it was explained that the packets under despatch were designed as a tentative measure of relief, and that other packets would follow only if the first consignment reached its destination in safety. The council of the Pharmaceutical Society expressed hearty sympathy with the movement and promised to nominate members to the Committee and to give the fund every assistance.

A letter from Mr. Meredith Townsend is appended showing that there has been a fair response already to the request for instruments.

The following subscriptions to the fund have been received by Dr. H. A. Des Vœux, the treasurer, up to Tuesday evening last, in addition to subscriptions amounting to £469 5s. 6*d.*, which were acknowledged last week:—

The Irish Committee.

The Irish Committee has been very active already. This Committee, which was started under the ægis of the Royal Colleges of Physicians and Surgeons, includes, in addition to the Presidents and Vice-Presidents of those bodies, the Presidents of University College, Dublin, and the President and Vice-President of the Pharmaceutical Society, the following representative names:—Sir Charles Ball, Mr. G. D. Beggs, M.P.S.I., Mr. Alexander Blayney, Sir Charles Cameron, Sir Arthur Chance, Dr. J. M. Finny, Dr. C. E. FitzGerald, Right Hon. M. F. Cox, Sir Andrew Horne, Sir John Lentaigne, Professor Lindsay, Dr. James Little, Dr. J. C. McWalter, Sir John Moore, Sir Lambert Ormsby, Sir Thomas Myles, Mr. R. D. Purefoy, Dr. Walter Smith, Sir Robert Woods, and Dr. W. M. A. Wright. Dr. T. P. C. Kirkpatrick, Registrar of the Royal College of Physicians, and Dr. C. M. Benson, Secretary of the Royal College of Surgeons, to whom cheques may be made payable, are acting as honorary secretaries and treasurers.

The following is a preliminary list of subscriptions which have been received or promised to the Irish Fund:—

	£	*s.*	*d.*

THE APPEAL FOR SURGICAL INSTRUMENTS.

The following letter has been received from Mr. Meredith Townsend:—

SIR,—The appeal for surgical instruments made in your columns on behalf of Belgium doctors has met with a ready response, and I feel sure that the very urgent need for these has only to be more widely known for the Relief Committee to receive a greatly increased number. I ask especially for midwifery instruments, tooth forceps, scalpels, forceps of all descriptions, and scissors.

I enclose a list of those medical men and women who have up to the present given gifts.

I am, Sir, yours faithfully,
MEREDITH TOWNSEND,
Master of the Society of Apothecaries.
Apothecaries' Hall, Blackfriars, E.C., Dec. 1st, 1914.

Dr. Gardner, George-street, Falkirk; Lieutenant-Colonel Walsh, I.M.S., Heath House, St. Faith's, Norwich; Dr. G. Le Seelleur, Jersey; Dr. A. E. Fiddian, The Walk, Cardiff; Dr. John Douglas, Central-hill, Norwood; L.S.A.; Miss Igglesden, Torwood Villa, Torquay; Dr. Gregson, Lower Audley-street, Blackburn; Dr. W. Jack, Laurel Mount, Kendal; Dr. Eveline Cargill, Lansdown Lodge, Cheltenham; Dr. Campbell, Duns; Dr. Papillon, Brent Knoll; Mr. A. E. Tanner, Westminster Hospital, S.W.; Mr. J. B. Lawford, Harley-street, W.; Dr. Stormont, Tanworth-in-Arden, Birmingham; Dr. E. P. Hardey, Spring Bank, Hull; Surgeon-Major R. E. Heath, Bryn Adda, Eastbourne; Dr. W. B. Secretan, 10, Redlands-road, Reading; Dr. Hulbert, Highbury-grove, N.; Dr. F. Milnes Blumer, The Mount, Stafford; Dr. F. L. Ford, Rushmere, Wimbledon Common; Dr. Holden, Sudbury; Dr. Grierson, Dudley-street, Grimsby; Dr. Hurry, Westfield, Reading; Dr. Edith Serjeant, Waterloo-road, Wolverhampton; Dr. Ayling, Cowley Mansions, Brixton; Dr. Evershed, Harley-street, W.; Dr. Meredith Townsend, Upper Phillimore-place, W.; Dr. J. W. Bell, Portland-place, W.; Dr. Aitchison and Dr. Exton, Blackburn; Dr. S. E. Baxter, Wollaston, Wellingborough; Dr. Charles J. Renshaw, Beech Hurst, Ashton-on-Mersey; Dr. Herbert Marson, Stafford; Dr. N. S. Twist, Wakefield-road, Normanton; Dr. William Tibbles, Derby-road, Parkside, Nottingham; Surgeon-General F. J. Lilly, R.N., "Annandale," Woodland-grove, Weybridge; Sir Lauder Brunton, Stratford-place, W.; Dr. W. T. Scott, Banchory.

THE CLAIMS OF BRITISH SPAS.

(Continued from p. 1112.)

VI.—LEAMINGTON.

LEAMINGTON, in Warwickshire, is a dignified, peaceful town which possesses a quite classical history in regard to the healing qualities of its waters. These are saline and sulphated. The Pump Room well contains as much sodium chloride as 1245 parts per 100,000, together with calcium sulphate 248 parts, magnesium chloride 47 parts, and magnesium sulphate 125 parts. The presence of manganese and titanium has been noted. This chemical composition bears a resemblance to many well-known waters abroad, and, like most saline waters, those at Leamington are cold. They are employed both internally and externally, and according to the experience of those engaged in medical practice at Leamington are useful in both directions.

In regard to internal administration, perhaps the most important action of the waters is that on the bowels. They are decisively though not drastically aperient, relieving portal congestion and promoting the expulsion of toxic bodies. There is thus produced a healthy effect upon metabolism, and diseases of gouty origin come under favourable treatment at Leamington. In gastric disorders, also, Leamington waters do good apparently by clearing up the mucus on the gastric wall. In addition, and as might be expected from their chemical composition, these waters exercise a marked diuretic effect leading to an increase in the output of uric acid.

As regards external application there is a complete installation of baths, and there is an abundance of ways of administering the waters in this direction. These include, for example, saline baths, Nauheim baths, needle bath and douche, Aix and Vichy douche, and so on. In addition, there are the usual adjuncts to treatment—for example, electrical and radio-therapeutic applications, ionic medication—now found at all well-equipped hydropathic stations.

The country round is beautifully rural and soothing, and, of course, it includes many places full of historic attractions, as, for example, Kenilworth, Warwick, and Stratford-on-Avon. The social amenities are well provided for; there is an orchestra in the Pump Room in the winter and in the beautiful gardens adjoining the Pump Room and the Jephson gardens in the summer. The climate is described as mild and equable, warmer in winter and cooler in summer than the health resorts of Central Europe. The entire establishment is under the control of the town council.

VII.—STRATHPEFFER.

The reputation of Strathpeffer as a hydro-therapeutic station is based chiefly upon its remarkable sulphur waters and its peat or mud baths. Three years ago important developments took place at this spa chiefly in the direction of providing further accommodation for the increasing number of visitors. On that occasion one of our representatives was present, who thus had the opportunity of examining the systems of treatment adopted there. There are three sulphur wells and a chalybeate of the type of the "Stahlbrunnen" on the continent.

A typical analysis shows the presence of just over 2 grains per gallon of sodium sulphide in the sulphur wells, and about 19 cubic inches per gallon of sulphuretted hydrogen. In addition the water contains 38 grains per gallon of magnesium sulphate, 8 grains of magnesium carbonate, 2½ grains magnesium chloride, 5·8 grains sodium sulphate, and 12 grains calcium carbonate. Although strongly sulphuretted the water has a curiously cleansing effect upon the mouth owing to its alkaline constituents.

Primarily the reputation of Strathpeffer rests mainly upon successful results achieved in the treatment of chronic and subacute gout and rheumatism, rheumatoid arthritis (in certain stages), and chronic rheumatic affections of muscles and nerves, such as lumbago and sciatica, but the waters have been used with benefit also in chronic skin diseases, disorders of digestion, uterine troubles, and in functional nervous disorders. By means of an atomising apparatus a spray of the waters is obtained which when inhaled has given relief in the treatment of chronic and acute conditions of the respiratory passages. The waters are administered also in the form of douches, and the Plombières method of intestinal administration is available.

Strathpeffer is beautifully situated in a most picturesque part of the Highlands; the climate is seldom extreme in spite of the far-north situation. There is protection from the north by the slopes of

Ben Wyvis (3500 ft.), while the winds from the S. and S.W. are tempered by a broad belt of hills lying in these directions. It is a most attractive country of hills and glens.

Though a comparatively small place Strathpeffer is rapidly growing in favour as a health resort. It receives every year a wider patronage, which can only mean that its reputation in the treatment of certain maladies is increasing year by year, and that its waters and its air and beautiful surroundings do much good.

(To be continued.)

THE SERVICES.

ROYAL NAVAL VOLUNTEER RESERVE.

THE undermentioned has been appointed a Surgeon for temporary service in His Majesty's Fleet:—Miles Prior (dated Nov. 17th).

ARMY MEDICAL SERVICE.

Captain Sir Bertrand Edward Dawson, K.C.V.O., 2nd London General Hospital, Territorial Force, to be temporary Colonel (dated Nov. 21st).

ROYAL ARMY MEDICAL CORPS.

The undermentioned are granted temporary rank as follows whilst serving with the Allied Forces Base Hospital:—To be Majors: Arthur George Whitehorne-Cole, Bernard Hudson, and Philip Maynard Heath. To be Captains: Norman Duggan, Sidney Bertram Radley, and Ernest Digby Roberts. To be Lieutenants: Douglas Erith Derry, Oswald Tilson Dinnick, William Moore Shipworth Robinson, and Robert Henry Liscombe.

The undermentioned to be temporary Lieutenants:—Dated Oct. 9th: Samuel Ernest Picken. Dated Oct. 13th: Robert Stewart Taggart. Dated Oct. 21st: Joseph Greenfield Johnston. Dated Oct. 22nd: John Henry O'Neill. Dated Oct. 24th: Andrew Rowan Hamilton. Dated Oct. 26th: Herbert Emerson. Dated Nov. 5th: D'Arcy Rivers Warren Cowan. Dated Nov. 6th: Charles Frederick Constant. Dated Nov. 9th: Ernest Frederic Westmore Buckell. Dated Nov. 10th: Richard Orthin Hilton Jones. Dated Nov. 11th: Richard Lavington Barwick, John Ivison Russell, and Harold Turley Mant. Dated Nov. 12th: George Edward Miles. Dated Nov. 13th: James Bertram Mitton and James Parnell O'Flynn. Dated Nov. 14th: William Elwood, Kenneth John Yeo, Arthur Norman Hooper, Walter Herman Kiep, Frederick Carson, and Alexander John Kendrew. Dated Nov. 16th: Horace Powell Winsbury White, George Dugal Yates, Francis John Morris, Philip Lys Davies, Robert Clephane Maclachlan, Arthur Eisdell Moore, Albert Edward Mortimer Woolf, and Athelstane Nobbs. Dated Nov. 17th: Maurice Colman Turiansky and John Barugh Fisher. Dated Nov. 18th: Wallis Charles Palmer Bremner, Archibald Lang McLean, Andrew Banks Raffle, and Henry Catling. Dated Nov. 19th: Thomas Francis Murphy. Dated Nov. 21st: Cecil Clarke, Peterswald Pattison, and John Ingram Shepherd.

The undermentioned Lieutenants resign their temporary commissions:—Dated Nov. 28th: Robert D. M. Macpherson and John B. Moore.

INDIAN MEDICAL SERVICE.

Major M. M. Lowsley, R.A.M.C., commanding Station Hospital, and civil surgeon, Kasauli, has been appointed to the medical charge of the Lawrence Military Asylum, Sanawar. Major T. H. Gloster and Captain J. Taylor have reverted to military employ.

TERRITORIAL FORCE.

Royal Army Medical Corps.

London Mounted Brigade Field Ambulance: Frederick Powlett Rankin, Thomas W. S. Paterson, and Edward B. Hartnell to be Lieutenants.

Yorkshire Mounted Brigade Field Ambulance: William Herbert Nairne White to be Lieutenant.

1st Home Counties Field Ambulance: Hugh Salisbury Palmer to be Lieutenant.

1st Lowland Field Ambulance: Lieutenant-Colonel William Francis Somerville, Retired List (late of this Unit), to be Lieutenant-Colonel.

1st North Midland Field Ambulance: Francis Grey Bennett to be Lieutenant.

3rd North Midland Field Ambulance: Cadet Stanley Sextus Barrymore Harrison, from the London University Contingent, Senior Division, Officers Training Corps H. Dunmore Lane, and John G. J. Green to be Lieutenants.

3rd Northumbrian Field Ambulance: Captain Oswald L. Appleton to be Major (temporary).

1st West Riding Field Ambulance: To be Lieutenants: Frederick Joseph Stansfield, John Clifford Metcalfe, and Frank Wigglesworth.

2nd East Anglian Field Ambulance: Captain Alister C. Young, from the 1st East Anglian Field Ambulance, to be Captain.

2nd East Lancashire Field Ambulance: To be Lieutenants: William Turner and Alexander Muir Gibson.

1st South Midland Field Ambulance: Captain Hans F. W. Boeddicker to be Major (temporary).

1st Eastern General Hospital: Major Henry B. Roderick, from the Unattached List for the Territorial Force, to be Major.

3rd South Midland Field Ambulance: The undermentioned Captains to be Majors (temporary): Thomas A. Green and Percy Moxey. Richard Irving Dacre to be Lieutenant.

Highland Mounted Brigade Field Ambulance: Andrew Mowat (late Lieutenant, 5th Battalion, Seaforth Highlanders) to be Captain (temporary). Thomas Ernest Roberts to be Lieutenant.

2nd North Midland Field Ambulance: Thomas Graham to be Lieutenant.

3rd West Riding Field Ambulance: Charles William Smith to be Lieutenant.

2nd Welsh Field Ambulance: Captain Henry T. Samuel to be Major.

4th London General Hospital: Charles Edward Hamilton Milner to be Lieutenant.

2nd Western General Hospital: James Barlow Macalpine to be Captain. Manfred Moritz to be Lieutenant.

1st London (City of London) Sanitary Company: John Horatio Baldwin and Evelyn Ashley Cooper to be Lieutenants.

Sanitary Service: Captain Harry Hunter resigns his commission.

West Riding Clearing Hospital: The undermentioned to be Lieutenants: Frederick Peter Gibson, Hubert Tunstall Bates, Jeffery Wentworth Malim, and George Percy Parker Clapham.

Attached to Units other than Medical Units.—To be Majors: Surgeon-Captain James Wilson, from the Pembroke (Castlemartin) Yeomanry, and Surgeon Captain Abraham Thomas, from 2nd Welsh Brigade, Royal Field Artillery. To be Captains: Lieutenant Harold W. Read, Lieutenant Stanley L. Brimblecombe, and Captain Charles Henry Reginald Pentreath, New Zealand Medical Corps. To be Lieutenants: Alexander Ambrose, Ernest Beresford Keen (late Lieutenant, 13th (County of London) Princess Louise's Kensington Battalion, The London Regiment), George Candler, Lieutenant Harold K. Griffith, from the Unattached List, for the Territorial Force, Andrew Perlane Granger, and Kenneth Mackinnon (late Lieutenant R.A.M.C. Territorial Force).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Captain William A. Hooton, from 2nd Western General Hospital, to be Captain.

VOLUNTEER FORCE.

2nd Volunteer Battalion, The King's (Shropshire Light Infantry): Surgeon Lieutenant-Colonel George Hollies is granted the honorary rank of Surgeon-Colonel (dated March 31st, 1908).

Forty-four Indian Medical Service officers have just reverted to military employ. The total number of officers thus reverting now amounts to over 200.

EDINBURGH UNIVERSITY: CHAIR OF MEDICINE.—At a meeting of the Curators of Patronage held on Nov. 30th the resignation of Professor John Wyllie, who had held the chair since 1900, was intimated. The curators have authorised their secretary, Mr. A. B. Fleming, W.S., 4, Albyn-place, Edinburgh, to receive applications from intending candidates up to Jan. 15th, 1915.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION.—The inaugural meeting of this association for the session 1914–15 was held on Nov. 28th, when the incoming President, Dr. J. T. Wigham, gave an interesting address on the Influence of Science on Modern Medicine. In the subsequent discussion it was stated that no less than 130 members of the association were at present serving with the colours.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 7943 births and 5760 deaths were registered during the week ended Saturday, Nov. 28th. The annual rate of mortality in these towns, which had been 13·4, 13·0, and 14·3 per 1000 in the three preceding weeks, rose in the week under notice to 16·6 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 14·0, against 14·3 per 1000 in the metropolis. Among the several towns the death-rate last week ranged from 5·2 in Ilford, 7·5 in Reading, 8·5 in Enfield, 8·7 in Lincoln, and 8·8 in Hornsey, to 23·2 in Rhondda, 23·3 in Newcastle-on-Tyne, 23·6 in Liverpool, 24·8 in Plymouth, and 25·5 in Rotherham.

The 5760 deaths from all causes were 794 in excess of the number in the previous week, and included 448 which were referred to the principal epidemic diseases, against numbers declining from 497 to 440 in the three preceding weeks. Of these 448 deaths, 174 resulted from measles, 102 from infantile diarrhœal diseases, 77 from diphtheria, 42 each from whooping-cough and scarlet fever, and 11 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3 per 1000, and coincided with that recorded in each of the two preceding weeks. The deaths attributed to measles, which had been 146, 167, and 148 in the three preceding weeks, rose to 174 last week, and caused the highest annual death-rates of 1·2 in Liverpool, 1·3 in Preston and in Rhondda, 1·4 in Plymouth, 2·1 in Oldham, 2·4 in Wallasey, 4·0 in Wigan, and 5·1 in Newcastle-on-Tyne. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 169, 131, and 138 in the three preceding weeks, fell to 102 last week, and included 28 in London, 8 each in Birmingham and Manchester, and 7 in Liverpool. The fatal cases of diphtheria, which had been 93, 58, and 74 in the three preceding weeks, rose to 77 last week, of which 24 belonged to London, 6 to Birmingham, and 3 each to Bristol, Liverpool, and Oldham. The deaths attributed to whooping-cough, which had been 38, 39, and 35 in the three preceding weeks, rose to 42 last week, of which 6 were recorded in Bristol, 5 each in London and Liverpool, 3 in Leeds, and 2 in Rhondda. The deaths referred to scarlet fever, which had been 34, 42, and 28 in the three preceding weeks, rose to 42 last week, and included 14 in London, 3 each in Birmingham and Manchester, and 2 each in Southampton, Smethwick, Warrington, and Newcastle-on-Tyne. The fatal cases of enteric fever numbered 11, against 17 in each of the three preceding weeks, and included 3 in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 5005 in the 14 preceding weeks, had further risen to 5035 on Saturday last; 623 new cases were admitted during the week, against 690, 751, and 627 in the three preceding weeks. These hospitals also contained on Saturday last 1653 cases of diphtheria, 63 of enteric fever, 56 of whooping-cough, and 50 of measles, but not one of small-pox. The 1424 deaths from all causes in London were 160 in excess of the number in the previous week, and corresponded to an annual death-rate of 16·4 per 1000. The deaths referred to diseases of the respiratory system, which had been 193, 181, and 203 in the three preceding weeks, further rose to 324 in the week under notice, and were 110 above the number recorded in the corresponding week of last year.

Of the 5760 deaths from all causes in the 97 towns, 213 resulted from different forms of violence and 418 were the subject of coroners' inquests, while 1539 occurred in public institutions. The causes of 54, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Sheffield, Leeds, Bristol, Hull, and in 56 other smaller towns. Of the 54 uncertified causes of death, 13 were registered in Birmingham, 10 in Liverpool, 5 in Bootle, 3 each in St. Helens and Blackburn, and 2 each in Warrington, Blackpool, Darlington, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1093 births and 808 deaths were registered during the week ended Saturday, Nov. 28th. The annual rate of mortality in these towns, which had been 15·8, 15·2, and 16·6 per 1000 in the three preceding weeks, further increased to 18·4 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 15·8, against 14·0 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 7·6 in Kirkcaldy, 8·8 in Motherwell, and 13·5 in Edinburgh, to 21·5 in Perth, 24·3 in Hamilton, and 24·9 in Dundee.

The 808 deaths from all causes were 78 in excess of the number in the previous week, and included 82 which were referred to the principal epidemic diseases, against 50 and 69 in the two preceding weeks. Of these 82 deaths, 25 each resulted from scarlet fever and whooping-cough, 13 from diphtheria, 10 from infantile diarrhœa, 5 from measles, and 4 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·9, against 1·3 per 1000 in the 97 large English towns. The deaths attributed to scarlet fever, which had been 17, 8, and 16 in the three preceding weeks, further rose to 25 last week, of which 13 were registered in Glasgow, 6 in Aberdeen, and 3 in Dundee. The deaths referred to whooping-cough, which had been 12, 7, and 13 in the three preceding weeks, further rose to 25 last week, and included 22 in Glasgow. The fatal cases of diphtheria, which had been 18, 7, and 17 in the three preceding weeks, fell to 13 last week; 6 deaths occurred in Edinburgh, 3 in Glasgow, and 2 in Aberdeen. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had declined from 31 to 19 in the five preceding weeks, further fell to 10 last week, and included 6 in Glasgow and 2 in Dundee. The 5 deaths referred to measles were 3 in excess of the average in the earlier weeks of the quarter, and comprised 2 each in Dundee and Aberdeen and 1 in Glasgow. The 4 fatal cases of enteric fever were equal to the average in recent weeks, but showed no excess in any town.

The deaths referred to diseases of the respiratory system, which had steadily increased from 62 to 112 in the ten preceding weeks, further rose to 163 in the week under notice; 39 deaths resulted from different forms of violence, against 32 and 26 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 594 births and 449 deaths were registered during the week ended Saturday, Nov. 28th. The annual rate of mortality in these towns, which had been 18·2, 17·7, and 18·3 per 1000 in the three preceding weeks, further rose to 19·4 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 17·0, against corresponding rates of 14·0 and 15·8 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 18·9 in Dublin (against 16·4 in London and 19·8 in Glasgow), 20·8 in Belfast, 19·7 in Cork, 15·2 in Londonderry, 19·0 in Limerick, and 20·9 in Waterford, while in the 21 smaller towns the mean death-rate was 18·5 per 1000.

The 449 deaths from all causes were 26 in excess of the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 40 and 44 in the two preceding weeks. Of these 40 deaths, 14 resulted from measles, 10 from scarlet ever, 10 from infantile diarrhœal diseases, 3 from whooping-cough, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·7, against corresponding rates of 1·3 and 1·9 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 11, 9, and 10 in the three preceding weeks, rose to 14 last week, and were all registered in Belfast. The deaths referred to scarlet fever, which had been 6, 14, and 12 in the three preceding weeks, further fell to 10 last week, and included 3 each in Belfast and Waterford and 2 in Lisburn. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 21, 10, and 13 in the three preceding weeks, fell to 10 last week, of which 3 each were recorded in Dublin and Belfast. The 3 deaths attributed to whooping-cough were slightly below the average in the earlier weeks of the quarter, and comprised 2 in Cork and 1 in Belfast. The deaths from diphtheria occurred in Dublin and Cork, and the fatal case of enteric fever in Belfast. In addition to the above a death from typhus was registered in Dublin.

The deaths referred to diseases of the respiratory system, which had been 86, 67, and 85 in the three preceding weeks, further rose to 100 in the week under notice. Of the 449 deaths from all causes, 149, or 33 per cent., occurred in public institutions, and 17 resulted from various forms of violence. The causes of 22, or 4·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion did not exceed 0·9 per cent.

INDIA.

(FROM OUR OWN CORRESPONDENTS.)

St. John Ambulance War Fund.

THE headquarters St. John Ambulance War Fund for India publishes a list of donors to Oct. 27th, showing total subscriptions amounting to Rs.60,167.10.9; also a statement showing that the Freemasons of Northern India have contributed no less than Rs.3,334.11.0 to the Fund.

Red Cross War Gifts.

The generous undertaking given by the Indian railways to transport the Red Cross war gifts free over their respective railways has undoubtedly proved of much advantage. Every through train arriving at Victoria and Colaba terminus, Bombay, brings in many neatly packed cases marked with the "Red Cross." A large number of these gifts have been sent with the transports that have already left.

Red Cross Kit Bags.

A letter recently issued by the Indian St. John Ambulance Association gives details of a scheme for providing Red Cross kit bags with extra clothes and comforts for Indian soldiers on leaving hospital, which has received the approval of the Director of Medical Services in India. It is estimated that a thousand of these bags, at a cost of Rs.16 each, will be required monthly. It is intended to present one to each invalided soldier either on departure from Egypt or East Africa for India or on arrival at Bombay. It is also proposed to offer a supply of these bags to the hospitals for Indian soldiers in England.

The "Emden" and Town Planning.

Professor Geddes, accompanied by his son, has come to India in connexion with the approaching town-planning exhibitions in the leading cities of India. It is said that the consignments of models, drawings, plans, maps, and pictures, intended for use in connexion with the exhibitions, have been lost in the sinking of the *Chilkana* by the *Emden*. The exhibitions will, however, be held as arranged, and efforts are being made by Professor Geddes, both here and in England, to replace as many of these things as possible. Local efforts are also being made in the same direction, and it is expected that the exhibitions will be pushed through.

Bombay School of Tropical Medicine.

With reference to the scheme for the establishment of a school of tropical medicine and hygiene in Bombay, the Government have finally decided to establish the school in conjunction with the Bombay Bacteriological Laboratory at Parel, but the clinical materials available in the hospitals which are associated with the Grant Medical College should be utilised to the fullest extent possible for the instruction of students at the school.

Indian Medical Service Appointment.

Major D. McCay, I.M.S., professor of physiology, Medical College, Calcutta, is appointed to act as resident surgeon of College Hospital, in addition to his own duties, with effect from Sept. 17th.

Nov. 4th.

Correspondence.

"Audi alteram partem."

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

To the Editor of THE LANCET.

SIR,—I earnestly hope that this most deserving fund will meet with a hearty support from the profession. It has special claims upon some of us. Nearly a thousand practitioners in Great Britain are medical graduates of the University of Brussels, and it is to be hoped that few of them will forget their Belgian fellow graduates in the time of their adversity. A small contribution from every doctor of medicine of the University of Brussels in this country would be of considerable assistance, and could be well afforded by most.

In July, 1899, at the annual dinner of the Brussels Medical Graduates' Association, Dr. C. Burland, of Liverpool, being the then President, a complimentary telegram was sent to the King of the Belgians, and a courteous reply received from His Majesty before the festival ended. Surely the well-wishes expressed by the representatives of British practitioners with the Brussels degrees to the head of the Belgian State meant something more than mere hollow phrases of courtesy. They were then intended to show the regard of Brussels medical graduates for the University that had conferred their degrees, and their respect for the Government, and beautiful city, now trodden down by an insolent foe, that had created that University. Is it, then, too much to ask every Brussels medical graduate in this country to give a donation to this fund, if only to prove that the expressions of their representatives in 1899 to the King of the Belgians were sincere and honest, rather than hollow, meaningless words?—I am, Sir, yours faithfully,

MAJOR GREENWOOD, M.D.Brux., LL.B.Lond.

Hackney-road, N.E., Nov. 27th, 1914.

"STRUMOUS HABIT OF BODY."

To the Editor of THE LANCET.

SIR,—It would be interesting to know what Sir Dyce Duckworth, in his address before the Hunterian Society, published in THE LANCET of last week, precisely means by "strumous habit of body." The word "strumous" is probably unknown to the present-day generation of medical students, the term having been expunged some time ago from the index of diseases of the Royal College of Physicians of London. Older practitioners will remember that struma was applied to a type of diseases the cause of which was afterwards proved by Koch to be due to the tubercle bacillus; hence all disorders of this nature became known as tuberculous. But if by "strumous habit of body" Sir Dyce Duckworth recognises a pre-tuberculous state, especially identified with and necessary to the subsequent evolution of tubercle, reasons exist for believing that the term is misleading.

A so-called strumous person of former times, one in whom no active tubercle was present, showed evidence of a sluggish circulation, with cold, bluish, and often more or less swollen extremities, of pronounced liability to pus infections indicative of diminished resistance, to ulceration of the cornea, to certain chronic dermatoses, such as eczema, psoriasis, and sclerodermia, and thus without any evidence of tubercle these signs were described as strumous, in common with tuberculous glands, joints, and other forms of tuberculous disease. The advance, however, of modern medicine has thrown light upon these so-called strumous symptoms, which are not tuberculous. The signs, in short, are evidence of perverted metabolism, due to hypothyroidism, the proof of which is furnished by the fact that under thyroid treatment these "strumous" symptoms vanish. In cases among out-patients with ulceration of the cornea, corresponding to the former "strumous ophthalmia" type, and with the general signs of "struma," the improvement is rapid and permanent under the influence of thyroid extract. Apart from the local treatment, no other drug or preparation was used by me. In the course of testing the effect of thyroid treatment in eye disease, it is in this class of cases that I have found the results to be the most beneficial.

I am, Sir, yours faithfully,

London, W., Dec. 1st, 1914. PERCY DUNN.

THE POSITION OF BELGIAN DOCTORS.

To the Editor of THE LANCET.

SIR,—"At least 1000 of the doctors are now absolutely poverty-stricken, and 2000 to 3500 are suffering cruelly through this war," so writes Professor Jacobs, of Brussels. Let us turn now to THE LANCET of Oct. 3rd, and we are told that £90,000 (of the unallotted funds of 1913) have been divided amongst 1500 doctors in London alone. Eminent counsel and public opinion assert that the doctors have neither moral nor legal right to the possession of that money. The unallotted funds for 1913 were probably £200,000 or more; we surely are all agreed that not one penny of this rightly belongs to us. Our Belgian *confrères* have lost all but their soul, and the soul of our nation is certainly awakened. By returning that money, to which we have neither moral nor legal right, for the use of our Belgian colleagues we have opportunity of coming into line and showing that the soul of our profession is also awakened.

I am, Sir, yours faithfully,

Nottingham, Nov. 24th, 1914. J. A. OSWALD BRIGGS.

THE LATE MR. C. B. LOCKWOOD.

To the Editor of THE LANCET.

SIR,—As one who for 30 years was on terms of close intimacy with the late Mr. C. B. Lockwood, may I be permitted to add a few words to the excellent notice of his career lately published in your columns? My friendship with Lockwood dates back to his early student days, and I am well acquainted with the hard work and struggles he had to contend with. His long period of service in the dissecting-rooms, while it laid the foundation of great anatomical knowledge and subsequent surgical skill, also permanently damaged his health to an extent probably known only by myself. Lockwood often referred to this in conversation, and asserted he never recovered full health and vigour. To this cause may undoubtedly be ascribed those occasional asperities of manner which caused one of the kindest men to be feared by students in the wards or examination rooms. He was a great student of Napoleonic literature, and a good conversationalist. For many years we walked in the country on Sundays, a habit which we estimated tended to preserve health, during the hardships of early professional life in London, known only to those who have not the support of money or powerful friends. In later years we took sporting expeditions together in the too brief autumn holidays. I assisted at the landing of a 47 lb. Norwegian salmon, an achievement which ranked as high in Lockwood's estimation as some of his most important surgical achievements. We were also co-examiners to the Apothecaries' Company. Lockwood's devotion to St. Bartholomew's was extreme, and he once referred to the institution I had the honour of serving, as a "cottage hospital somewhere in the West-end!" He possessed in a prominent degree north country grit, and that love of sport and hospitality inherent in the Yorkshireman. He constantly entertained his friends, his house surgeons, and dressers. He was a fair fisherman and a good shot, and possessed a famous family of Dandie Dinmont terriers, not the least celebrated of which was my own faithful companion for many years.

Of Lockwood's great success as a surgeon it is needless for me to speak. I received much advice and a good deal of operative treatment from him in my own long and calamitous illness. He was especially known for his care and cleanliness, and was often employed in cases where avoidance of sepsis was of great importance. Hence the peculiar tragedy of his end, and it is singular we both should have suffered from the leading calamity of a surgical career in the form of different varieties of septic infection.

The news of his death came as a shock to myself and a circle of friends and old patients. The announcement of his funeral in the press, which was noticed too late for me to attend, was the first intimation I received of his decease. The students of his great hospital may copy the example of one who by work and indomitable perseverance attained to success, and who in his life exemplified the highest traditions of professional honour in his dealings with his brethren and the public.

I am, Sir, yours faithfully,

Dec. 1st, 1914. A. MARMADUKE SHEILD.

BIRDS AND MALARIA.

To the Editor of THE LANCET.

SIR,—The annotation entitled "The Duck as a Preventer of Yellow Fever and Malaria," which appeared in THE LANCET of Nov. 7th, directs attention to an interesting subject.

The experiments with water fowl carried out by Dr. Dixon, of Pennsylvania, are undoubtedly suggestive, but he was not, of course, the first to employ aquatic birds for the destruction of mosquito larvæ. Well-nigh a year ago[1] I reviewed a paper by Friedrichs on "Foreign and Native Mosquito-Destroying Fish," in the course of which he states that ducks, like fish, keep pools and ponds free from mosquito larvæ. Recently, when discussing this subject with Dr. Louis Sambon, Epidemiologist to the Wellcome Bureau of Scientific Research, he referred me to a paper of his,[2] published in 1902, wherein he mentions the larvivorous properties of water fowl. Dr. Sambon, who has an unrivalled knowledge of the historical literature both of tropical medicine and parasitology, has kindly given me the following extracts dealing with the part played by birds as destroyers of mosquitoes.

---

[1] Tropical Diseases Bulletin, vol. ii., No. 12.

[2] Remarks on the Nomenclature, Etiology, and Prophylaxis of the Intermittent Fevers, Journal of Tropical Medicine, Sept. 15th, 1902.

Beutenmüller, of the Museum of Natural History, New York, in his "Essay on the Destruction of the Mosquito and House Fly," and also in Lamborn's "Dragon Flies *v.* Mosquitoes," 1890 (pp. 117–120), says:—

> *Fish and Water Fowl.*
>
> I consider, in the second place in natural remedies, the importance of fish and water fowl for the subjection of the mosquito. These instrumentalities I regard as of very considerable importance, and amongst natural remedies place them as the equivalents of and possibly of more interest than the dragon fly. For in this connexion it must be remembered that a method which attacks at its inception is more likely to lead to radical results than one applied later, after the scourge has reached considerable dimensions, and is not so readily grasped. If the larval stages of the mosquito can be reached effectively we have nipped the disorder, as it were, in the bud. It is true that distinguished entomologists state that the dragon-fly in its water life attacks and destroys the larvæ of the mosquito, but I have no information on that point, though from the manner in which the larvæ of the dragon-fly destroy each other it seems probable that their carnivorous propensities might lead them to attack the young of mosquitoes. Yet in this case I think the injury inflicted on mosquitoes would be slight, and the larger number would escape. But young and old fish, and also aquatic birds, will devour them in great numbers where they occur in large masses, and the cultivation of these denizens of our pools and lakes is, therefore, most advisable, as striking means for the diminishment of these pests.
>
> Mr. Ludwig Riederer, of New York, informs me that he has dissected a fish caught in a fresh water lake, and found in its stomach hundreds of mosquito larvæ and pupæ. I said in the discussion of the problems that we might find it well to use some remedies, in some circumstances, that would preclude the use of others equally effective, while these latter would be again valuable under different conditions. Here is an illustration. Aquatic birds can be adopted for the purpose of destroying mosquito larvæ in ponds, rain-pools, &c., near houses, and in ponds in well-cleared fields, rolling and cultivated land, where there is no extent of wood, and management of the fowl can be made simple and their breeding profitable; and fish can be introduced in our public lakes. In these different provinces the different agents of this compound remedy will effect beneficial changes. It has been observed by myself how infrequent the larvæ are in the Central Park (New York City) lakes, and that their absence is due to the industry of the fresh water fowl, though there is another suggested cause which I will mention in a succeeding section. The obvious dissatisfaction over these remedies is their probable insufficiency; but as helpful and useful in the absence of more perfect means there is in my mind no doubt.

The use of birds for dealing with the *imagines* has also been advocated. Thus Weeks, writing in 1890 in Lamborn's book (*loc. cit.*), says:—

> Instead of devising methods to artificially breed disproportionate numbers of insectivorous insects, why is it not much more advisable to foster and preserve with little expense the means which we have at hand? I refer to the various species of insectivorous birds, which used to remain with us throughout the year, with the exception of two or three of the colder months, the most short-lived of which would be more effective in the destruction of noxious insects than 10,000 dragon flies.

In this connexion Dr. Sambon has been good enough to furnish me with an historical allusion which is very interesting and remarkable, and once more goes to prove the truth of the old saying that there is nothing new under the sun.

> Over a hundred years ago (exact date uncertain, but somewhere between 1790 and 1812) a Supplication was presented to the Sacred Tribunal in Rome by the Commune of Marsciano, Umbria, asking for a papal decree prohibiting the killing of nesting swallows for food because the destruction of these birds brought about the deterioration of the air, and hence insalubrity in the region. Two reasons were put forward in support of the contention. In the first place it was pointed out that swallows feed on the small flying insects which are so troublesome and hurtful to man and animals during the hot season, and secondly that by their frequent and rapid flight they produce a constant movement of the air which rarefies and purifies it. The petition was strongly endorsed by Dr. Giampiètro Picconi, the local physician, who stated that the destruction of insects by the swallows would not only prevent annoyance but remove a cause of sickness.
>
> In his report to the S. Consulta on this Supplication Dr. Domenico Morichini admits that swallows do feed on those insects which multiply exceedingly during summer time, especially in low marshy places. He quotes the great Italian naturalist, Spallanzani, who recommended the protection of these birds on account of their destruction of mosquitoes and other troublesome insects. He also believes that their flight may cause a useful ventilation and prevent those reactions of the atmospheric elements which are known to give rise to febrile miasmata. He states that for this very purpose the Trappensi monks of Casamari and Fossanuova always keep large quantities of pigeons to continually renovate and improve the unhealthy air of the malarious places they inhabit, and that they have obtained from the Popes the right to threaten excommunication and five years of imprisonment in irons to anyone who dared to kill their pigeons.

Doubtless many other instances could be cited but those given will serve to illustrate the subject to which you have drawn attention.

I am, Sir, yours faithfully,
ANDREW BALFOUR

Wellcome Bureau of Scientific Research, Henrietta-street,
Cavendish-square, W., Nov. 23rd, 1914.

A PLEA FOR MORE CONSERVATIVE TREATMENT OF UTERINE APPENDAGES.

To the Editor of THE LANCET.

SIR,—Mr. E. P. Furber, in a letter in your issue of Nov. 28th, has raised an important question, and one which shows, if demonstration be needed, that a sound pathological knowledge is one of the essential accomplishments of what may be called the "compleat" surgeon. The whole question of treatment in the case recorded should have depended on the nature of the infecting organism and the character of the lesions which it is known to produce.

The organism was found to be a streptococcus. Mr. Furber's diagnosis of the lesion produced, and I presume that of the other surgeons who saw the case—"pyosalpingo-oöphoritis"—could not have been correct. No woman who has had double pyosalpingo-oöphoritis (tubal abscesses) has ever recovered and borne children, at least without operation.

However, the point of the case is that the patient was infected by streptococci, and if in these circumstances there be salpingitis without the formation of pyosalpinges a perfect functional result may ensue.

I emphasised this point in my "Principles of Gynæcology" (1910), where I made the following statement on p. 269: "It must not be forgotten, however, that staphylococcal and streptococcal infections do not destroy the mucous surfaces of the tubes in the way that gonococcal infections do; consequently complete functional recovery may occur after puerperal infection."

I am, Sir, yours faithfully,
W. BLAIR BELL.

Liverpool, Nov. 30th, 1914.

SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—I should like to add one or two remarks to your annotation in THE LANCET of Nov. 14th on Professor Bang's paper on sanatorium treatment. It is not always possible to classify pulmonary tuberculosis or the results of its cure under different stages of the disease. Patients do not generally present a clear-cut, a well-defined first, second, or third stage when they come for treatment. The first stage often merges into the second, the second into the third. Even the classification into early, moderately advanced, and advanced stages may prove incorrect or misleading, as what one physician would consider early, another would call moderately advanced, and so on. Patients have been sent to me as early cases when they were really incurable and had to be sent home after a few days. Nor can the results of sanatorium treatment be tabulated according to the number of lobes involved, as a patient with four lobes slightly affected would be likely to get well, while another with only two lobes seriously diseased might succumb. Besides, as Dr. E. E. Prest pointed out in your last issue, very few patients are admitted into the sanatorium really in the first stage in spite of the Notification Act. No two patients are alike in the condition of their disease or in the extent of their cure. So that the present method of classification of sanatorium results is open to many fallacies which are apt to vitiate statistical figures brought forward to prove the efficacy of the treatment. In giving my results of sanatorium treatment published in my book on "Pulmonary Tuberculosis," I adopted a more practical plan and classified according to whether the patients sufficiently improved to return to work or not.

I agree with Professor Bang when he says that the results of some early cases are disappointing, while some advanced cases astonish one by getting well. Though the reason for this is rather obscure in a small number of cases, it is not difficult to explain in many others. Patients in the first stage handicapped with poor resistance and vicious surroundings often do badly, whereas those in the second stage with plenty of reserve vital powers do well and keep well. Again, it frequently happens that some patients apparently slightly affected think that there is very little the matter with them and do not carry out the treatment earnestly, but at the very first sign of return of health leave the sanatorium and take to their old ways and unhygienic lives when they get home, with the result that many of them relapse. But others though in an advanced stage, having suffered, and realising that their future as bread-winners depends upon the restoration of their health, do everything possible to get well and persevere in the treatment till they succeed. Also, as Dr. Prest has shown, many mild cases which are treated at home in a half-hearted and inefficient way drift into a chronic state, and when they do enter a sanatorium afterwards as first-stage cases do not make a satisfactory progress. So that the results of sanatorium treatment have more to do with such factors as the patient's resisting power, his perseverance, his means and his after-care, &c., than merely with the first, second, or third stage of the disease. When these factors are ignored or not taken into calculation, one is liable to blame the sanatorium treatment unjustly for any of its failure.

I am, Sir, yours faithfully,

Mendip Hills Sanatorium, Wells, Dec. 1st, 1914. C. MUTHU.

COAGULOSE.

To the Editor of THE LANCET.

SIR,—We observe that in some newspapers a statement appears regarding what is called a recent medical discovery by Professor Kocher, of Berne, who has introduced a substance called "coagulen," which coagulates the blood and instantly stops bleeding when applied to a wound internally or externally.

May we mention that the coagulating principle, or fibrin ferment, of the blood was isolated some years ago by a British scientist, Dr. G. H. A. Clowes, with whom was associated Dr. F. C. Busch, these two gentlemen working in the New York State Medical Research Laboratory, Buffalo. The preparation received the name of "coagulose," and it has been on the British market for more than a year. Immediately after war was declared Dr. Clowes, who happened to be in this country at the time, interviewed a number of medical men connected with the War Office, and he donated to the War Office a supply of coagulose, so that it might be employed in the hospitals where the wounded soldiers are being treated. We have reason to know that it is being used in some of these hospitals, and that it is producing excellent results.

While this does not in the least detract from the merit of Kocher's discovery, common fairness warrants us in asking you to make it quite clear that the announcement of this discovery was anticipated by at least three years by an Englishman working in America.

We are, Sir, yours faithfully,

London, W., Nov. 26th, 1914. PARKE, DAVIS, AND CO.

⁂ An annotation in THE LANCET of April 11th of this year entitled "A New Physiological Hæmostatic" may be consulted.—ED. L.

THE NATIONAL INSURANCE ACT.

MEDICAL TREATMENT OF INSURED PERSONS CALLED UP FOR SERVICE WITH HIS MAJESTY'S FORCES.

THE Insurance Commissioners, in response to requests for information as to the medical treatment during the war of insured persons who belong to the Naval or Army Reserve, or to the Territorial Forces, or have enlisted in the New Army, have issued a memorandum for the use of medical practitioners. This states that such persons generally are regarded as serving sailors or soldiers from the moment at which they are called up, or enlisted, and accepted for service until disembodiment or discharge. During this period they are not entitled to medical or sanatorium benefits under the National Insurance Acts, and accordingly no liability for their treatment rests on the panel practitioners by whom they have been accepted. The position of such persons is not affected by the fact that they may be permitted temporarily to continue to reside at home, even though they may be concurrently engaged in civil employment. An insured person who has been sent home owing to illness, or in consequence of having been wounded, must also be regarded as a serving sailor or soldier until the date of his discharge.

A member of the Naval or Army Reserve, Territorial Force, or New Army, who, while not entitled to treatment under the National Insurance Acts, applies for treatment to a practitioner on the panel or to an Insurance Committee, should be dealt with as follows:—

1. A member of the Naval Reserves should be referred to the naval surgeon and agent, if there is one in the district, and in the absence of a naval surgeon and agent should be directed to make his own arrangements with a qualified civil practitioner for treatment. In the former case the surgeon and agent will receive his fees from the Admiralty; in the latter the patient will be responsible for settling the doctor's charges, but will be eligible to receive sick allowance under the King's Regulations and Admiralty instructions on making application for the same through his commanding officer.

2. A member of the Army Reserve, Territorial Force, or New Army on furlough should be referred to the officer commanding the nearest military station, who in every case will communicate with the Assistant Director of Medical Services of the area in which the soldier is temporarily residing. In case of emergency, or when a soldier unfit to travel resides at a distance from a military hospital, the soldier may apply to a civil practitioner to whom he will show his furlough paper, and who will be allowed to charge for attendance at the rate laid down under Army Regulations (A.F. O. 1667), provided that the soldier immediately reports to the officer commanding the nearest military station, as directed above.
